The concept of hope-healing communities is used by the present author elsewhere [9b] to refer to those interfaith (Christian) prayer-healing ministries aimed at using the power of the Christian prayer and other rituals of religion to bring God's intervention and healing to the needy. The bulk of the members of those communities are the sick, the disabled, the poor, the jobless, the childless, the old, and the other categories of the general society who are deeply troubled by how their lives have been going. The leaders/organizers of such communities are typically ordained religious ministers, most of them well trained in the ramifications of African thought and culture and in the art and practice of the healing sciences. They include some charismatic Catholic priests as well as bishops and other ordained ministers of the African Independent/Pentecostal churches. Others, particularly those popular in the rural areas, are lay members (some of them well trained in the science of modern counseling practice) who claim to have received the "call" to intercede and act as a channel of healing for the sick.

Hopi Religion and Anthropology

Description

The Hopi Indians have a Pueblo culture in Southwestern United States, at the northeastern corner of Arizona, east of the Grand Canyon in the Painted Desert Region. Approximately 12,000 Hopis live in 12 villages on the southern edge of Black Mesa, which is a part of the Colorado Plateau. With the exception of one town near Tuba City, the villages rest on or at the base of three mesas called First, Second, and Third mesas. In the fertile sand valleys, the Hopis grow a variety of crops, primarily maize, beans, melons, and squash using floodwater farming methods. In the grassy areas, they herd sheep and cattle as well. Many have jobs on and off the reservation, but they still supplement their economy and subsistence with farming and gathering.

The Hopis speak a language belonging to the Uto-Aztecan language family. Today most Hopis also speak English. They have been living in the area at least since 1000 A.D. The villages of Songoopavi and Orayvi both claim to be the oldest continuously inhabited villages in North America. They were under the influence of Spain from 1600 to 1700, independent until a brief period under Mexico (1821–1848) and since 1849 under the United States. The Hopi Reservation was established in 1882, and in 1935, the Hopis established a Tribal Council. The Council was disbanded in 1940, but reestablished in 1951 in order to receive monetary compensation under the Indian Claims Commission Act.

The Hopi social system is based on matrilineal, exogamous totemic clans grouped in phratry coalitions. Children are members of their mother's clan by birth. Clans are subdivided into lineages, and the core social group is the household which consists of the mother, her children, her husband, and elderly grandparents. Each clan has its own oral tradition, ritual practices, and property with privileges related to special places and (animal and/or supernatural) creatures in the environment. The clan performs rituals and ceremonies that are conducted in the kivas (buildings that serve as chapels as well as men's clubs) that are the men's domains. The ceremonial year is orchestrated by a large number of secret sodalities. The leaders of sodalities and leaders appointed by the clans govern the village under the guidance of the village chief.

The Hopis still practice their traditional religion; however, only one village (Songoopavi) performs the entire ceremonial calendar. Remnants of ceremonies and rituals are still performed at the other villages. The popular masked dance ceremony (Katsina) is performed at virtually every village. All children must be initiated into either the Katsina or the Powamuy sodality in order to perform the Katsina celebrations when they grow older. The other sodalities are more restricted and require their own initiation rituals. The Hopis are well known for their colorful and elaborate ceremonies which consist of at least 12 major and a number of minor ceremonies. They are conducted in sets of 4 days (4 being a sacred number), thus: 4, 8, 16, and exceptionally 20 days.

One of the most spectacular ceremonies is the Snake Dance, celebrated in August, during which the Snake priests dance with live snakes in their mouths. Since these are dangerous rattlesnakes and bull snakes, the Hopis have been inundated with curious tourists ever since the end of the nineteenth century. During the middle of the twentieth century, the Hopis began to bar the presence of non-Indians, although the Tribe is split on the issue. In 1906, the village of Orayvi split over the issue of whether to accept Anglo-American ways (Titiev 1992; Whiteley 1988). The conservative element was forced out of the

village and they established the villages of Hotvela and Paaqavi. Since the late 1940s, the conservative elements started a neo-traditionalist movement which led to a lot of factional strife on the reservation. The Traditionalists were often supported by outside Anglo-American fringe groups and new religious movements who have unwittingly but consistently misrepresented Hopi religious traditions in terms of their own romantic notions. Today, many wrong ideas about Hopi religion are being promulgated by New Age and other groups, especially on the Internet (Geertz 1994). The Hopi Tribe has implemented an aggressive policy to correct such ideas and prevent further interference from outside groups. They are also adamant about regaining all Hopi ritual and funerary items found in museums around the world.

Self-Identification

Religion

The Hopis identify themselves as a religious and cultural group and practicing the Hopi way of living (*hopivewa*) as dictated by their tutelary deity Maasaw in primordial times. For the Hopis, the ideal way of life is the ritual way of life (Geertz 1986).

Characteristics

Hopi religion is only practiced by the Hopis. Some Hopis are members of other traditions, such as Mormonism, Jehovah's Witnesses, and various Christian denominations, but by far, the majority are either passive participants or active practitioners of the Hopi religion.

Relevance to Science and Religion

The Hopi Tribe is not interested in the scholarly area called science and religion. The Tribe is in fact very much against scholarly interest in their religion and have attempted to prevent scholarly studies of their culture and religion, although individual Hopis may be interested in such

studies (Geertz 1996). The Tribe is, however, interested in the sciences, especially where the sciences can help improve conditions on the reservation. The Hopis have their own anthropologists and archaeologists who take care of Hopi needs on the reservation in a culturally sensitive fashion. There are also Hopi anthropologists and linguists employed at American universities who serve as cultural resource persons for scholars interested in Hopi culture. The Hopi dictionary project was an excellent example of collaboration between cultural resource persons, other scholars, the Hopi Tribe and elders, and specialists among the Hopis (The Hopi Dictionary Project 1998).

Sources of Authority

The sources of authority are either Maasaw or the ancestors. Each clan has a special relationship with a particular creature or deity. For instance, the Bear Clan, which controls the Village Chief office, has a special, that is, ritual relationship with the bear, bear spirits, and a mythical person called Matsito. Tradition, however, is generally passed down from generation to generation by nameless ancestors. The traditions concern the wanderings of the clan after the emergence of mankind from the earth (physically located by the Hopis in a tributary channel of the Grand Canyon), who they met, and where they stayed on their travels to Hopiland. Upon approaching Hopiland, they were given permission by the Chief to move into the village and allotted portions of farmland on the condition that they contribute to the collective ceremonial calendar with their ritual knowledge and songs. All the clans, furthermore, share in the expectation that their White Brother, who left them shortly after the emergence, will return and signal the onset of the end of the world, a day of purification effectuated by Maasaw (Geertz 1984).

Ethical Principles

Hopi ethics can be summed up in their name: Hopi means “a person who behaves properly,”

in other words, a person who follows Hopi precepts, is hardworking, industrious, peaceful, and kind. Such a person is also initiated into clan and sodality knowledge and is thus able to perform the rituals necessary to maintain life and social harmony. There are people who try to destroy social harmony. They are the wizards and witches, called *powaq* (*pl. popwaqt*) (Malotki and Gary 2001).

Key Values

The Hopis place great emphasis on family and clan. The elders often identify themselves with their mythical ancestors. For example, during a BIA commission visit to the reservation in 1955, a leading clan member addressed the commission chairman as if both the chairman and he were the original White and Hopi brothers just after the emergence of mankind. The Hopis place great value on their land. They have intimate knowledge of the land and identify with it.

Conceptualization

Nature/World

As mentioned, each clan has a special relationship with creatures, animals, and natural phenomena. Thus, there are clans such as Bear, Badger, Antelope, Spider, Snake, Sand, Cloud, Water, and Corn. Each clan has ritual responsibilities to their particular totem. By performing rituals and ceremonies, the Hopis feel that they can influence the weather and other aspects of the world.

Human Being

The ideal human being is a ritual human being – a person who has a good heart and purpose, who serves as ceremonial host, and who “works for life” (*pam qatsit aw hintsaki*); a person who lives a good life, passes through the four life stages, and ideally dies peacefully in his or her sleep. The ideal human being through his or her personal behavior can also influence the weather.

Life and Death

There are no known creation myths. Those that have been published in the early ethnographic literature are most likely influenced by eastern Pueblos. There is, however, an overwhelming number of emergence myths, in other words, myths about how humans have lived inside the earth and emerged through three prior worlds to this fourth world. Usually each world begins as a paradise, but ends by destruction ultimately caused by evil humans, thus forcing the population to travel up to the next world level.

Reality

There are no specific notions about reality, despite Benjamin Lee Whorf's claims that the Hopi cosmic forms "manifested/manifesting" replace our notions of space and time (see below on time).

Knowledge

Knowledge is a key notion in Hopi thought. As mentioned above, clans have in their possession knowledge about their origins, the world, various creatures and beings in the world, as well as specific rituals, songs, and paraphernalia which serve as Hopi social currency. Knowledge is in a fundamental sense, the basis for social status.

Truth

The Hopis are not particularly interested in "truth" in a philosophical sense. Their knowledge of the world has been truthfully passed down through generation after generation.

Perception

Perception plays no particular role in Hopi thought.

Time

The study of Hopi culture and language was greatly influenced by the primitivism of the first decades of the twentieth century. One of the main contributors to romanticized ideas about the Hopis was philosopher and linguist Benjamin Lee Whorf. His theory of linguistic relativity led him to make absurd claims about the Hopi language, which are still with us in popular and

semi-academic publications. His major claim was that the Hopi language is timeless. He wrote that the Hopis have no general notion or intuition of time and that their language contains "no words, grammatical forms, constructions or expressions that refer directly to what we call 'time,' or to past, present, or future, or to enduring or lasting" (Carroll 1956, 57). He made similar claims about Hopi conceptions of space and of reality, all of which have been directly disproven with thousands of examples by linguist Ekkehart Malotki (1979, 1983).

Consciousness

The Hopis are not philosophically concerned with consciousness.

Rationality/Reason

The Hopis are not philosophically concerned with rationality or reason.

Mystery

The Hopis have a very clear idea of the forces that influence the course of events in the world. The worlds of nature and society are under the influence of deities controlling death, fertility, and the earth. They also conceive of approximately 250 beings called Katsinas, which particularly influence the weather and are performed by costumed and masked dancers during the growing season. The Hopis also place great emphasis on their ancestors. There are also a variety of lesser creatures that influence Hopi life to a greater or lesser degree. Sodality priests and medicinemen and medicinewomen attempt to control or influence these nonhuman beings.

While stress is generally considered to have harmful effects, in small doses it may have positive effects. For example, flatworms exposed to sublethal heat are better able to withstand subsequent heat exposures, including ones

which are lethal to non-exposed flatworms. Similarly, plants which are slowly exposed to cold (a process called “hardening”) become inured and can withstand temperatures which would kill indoor plants. This process may be generalized to stress in mammals as well. While still controversial, the evidence is growing that exposure to moderate levels of stress, combined with rest periods, can result in what Dienstbier called “physiological toughening.” Indeed, a growing number of researchers have demonstrated this physiological toughening in humans – especially those who report psychological stress-related growth.

Sanctity of the individual; Qur'an

Like the other Abrahamic religions, Islam makes strong moral claims, rooted in the sanctity of the individual and in the bonds that unite a community not only synchronically but historically, linking past and future generations with the living present. Muhammad's revelatory experience, articulated in the Qur'an, is rooted in such moral claims, his God commanding allegiance but also rectitude. Beyond the obligation of support for one's brethren in the umma, the nexus to a transcendent God fostered reverence for nature and gratitude for culture, conceived as gifts of God's benevolence. Greek science, philosophy, medicine, and other arts were welcomed as the heirs of the Muslim conquerors settled down. So was the Hebraic heritage that illuminated the Quranic backstory. Also welcomed were Indian mathematics and astronomy; Byzantine art and engineering; Persian epic traditions and administrative practices; Christian and Hellenistic moral, mystical, and ascetic ideas and practices; and even the making of paper, first learned from Chinese prisoners of war after the Battle of Talas in 751. From China too came sericulture. Silk garments challenged the puritan side of the faith. But paper posed a subtler challenge; as works of Greek and other cultures were increasingly and eagerly translated into Arabic in the ninth and tenth centuries, their contents

were absorbed as part of the booty of conquest. There was useful medical and alchemical data and astrological technique. But with this came challenging ideas, thoughts about naturalism, free will, the eternity of the world.

Arabic culture, of course, had native sources of humanistic thinking – in the traditions of tribal councils, the desert and the hunt, the experiences of love and loss, and the odes of the sensuous and spirited pre-Islamic poets who celebrated such themes and often pictured their joys, their pride, and their hopeless struggles with fate. Nor was all that issued from Byzantium, Damascus, Alexandria, or Iran unequivocally humanistic: Greek antiquity could condone and encourage infanticide and pederasty in ways jarring to the sensibilities of prophetic moral monotheism. The monarchies and satrapies of ancient Iran and the East, the castes of India, the resignation of Buddhism, and the metempsychosis of Hinduism would not settle perfectly comfortably into a Muslim soldier's, merchant's, or Sufi's saddle. But conquest *was* broadening, and it was not long before Muslim, Jewish, and Christian physicians, under the aegis of an Islamic state, were exploring and enlarging the boundaries of Platonic and Aristotelian philosophy and logic, Galenic physiology, Ptolemaic cosmology, Euclidean and Apollonian geometry, and the sciences that underlay the useful arts of medicine, astrology, architecture, and mechanics.

Here the conquests were intellectual. The casualties were the commitments of an unexamined faith. Thinkers in the nascent Islamic civilization needed logic if they were to debate successfully with Greek thinkers in Damascus. They needed mathematics for all sorts of practical purposes. But logic and mathematics opened vast new potentials for understanding. Here the motto that Bacon would frame in the English renaissance proved effective in reverse: Power was knowledge! But knowledge brought with it issues of intellectual honesty and responsibility: the historian's dedication to fact, the belle lettrist's love of significant detail, the philosopher's commitment to accept truth where one could find it and follow where the argument might lead. Muslim thinkers

and scholars became not just men of letters and learning or practitioners of technique but intellectual explorers and adventurers for whom the world was a laboratory and man himself was both the problem and the solution, the inquirer and the repository of many a hidden answer and discovery.

Among the great figures of Islamic humanism were al-Khwarizmi (ca. 800–850), the mathematician who had worked in the Bayt al-Hikma (House of Learning) founded by the Caliph al-Ma'mun as a center of scholarship and translation and went on to lay out the scheme of arithmetic using what we now call Arabic numerals and to found key tools of algebra, bequeathing to posterity not only the name *al-jabr*, literally “forcing into place,” but also his own name, the root of our word algorithm, a mathematical procedure; al-Farabi (d. 950), the brilliant logician and social theorist who asked himself how scripture could argue cogently by way of threats of retribution and came to understand prophecy as the mediation of the higher truths of reason to a mass audience by way of the symbols that imagination could supply to rhetoric and law under the name of religion; the Ikhwan al-Safa or Brethren of Purity (fl. ca. 970), whose collection of encyclopedic essays popularized the new learning and embedded there a fable, *The Case of the Animals vs Man before the King of the Jinn*, as the vehicle of a trenchant Aesopian critique of human institutions and pretensions and a call to a higher, more cosmopolitan vision of human potential; Hamadhani (d. 1008), literary virtuoso and satirist, the self-styled “Innovation of the Age” who invented the *maqamah* or “encounter,” a mixed genre of poetry and prose, centered on the japes of a trickster antihero whose verbal pyrotechnics and irreverences light up the dark corners of obscurantism and hypocrisy that Hamadhani saw around him; Miskawayh (d. 1030), the historian, minister of state, and ethicist who sought in literature and learning the keys to a cultivated way of life and a mature and humane character; Avicenna (Ibn Sina, d. 1037), the philosopher/physician who sought to resolve the conflict between the contingency of the Qur'anic

world and the necessity of Aristotle's world by viewing nature as contingent in itself but necessary by reference to its Cause; al-Biruni (d. ca. 1050), the mathematician, cosmologist, historian, and mineralogist who learned Sanskrit and wrote a pioneering ethnography of the newly conquered realms of northern India; Ibn Tufayl (d. 1185/6), the Andalusian physician/philosopher who experimented in fiction with the image of a self-taught man, Hayy Ibn Yaqzan, growing up innocent of language, culture, and tradition, who would discover, without the aid or interference of human contact or institutions, the moral and spiritual truths that religions could only shroud in symbols and stud with the most minimal and undemanding norms; Ibn Khaldun (d. 1406), the Maghribi historian, failed politician, and political consultant on tribal affairs, who founded what he called a new science of civilization in seeking to understand the cultural underpinnings of human history.

What is humanistic about the traditions in which such figures as these and many others like al-Kindi, al-Razi, Sijistani, or Tawhidi stand out? These men do not typically resent or reject the religion which they grew up in or even chose. They are not secularists, nor are they liberal for the most part in any typically modern sense. But they pursue the value of personhood that they find in their religion, and they balance its asperities with a lambent commitment to intellectual freedom and personal creativity. Their values, literary, intellectualist, scientific, courtly, medical, even mercantile, leaven their spiritual heritage and allow them to interpret the obligations of the faith in ways affirmative of humanity. They and their achievements represent powerful alternatives to an outlook that has today made itself all too prominent as a reading of Islam and its relation to other faiths and practices, the salafist movement that seeks to recapture Islamic hegemony by returning to the practices of an imagined past.

Humanistic Movement/Values

Sarah A. Schnitker¹ and Robert A. Emmons²

¹School of Psychology, Fuller Theological Seminary, Pasadena, CA, USA

²Psychology Department, University of California, Davis, Davis, CA, USA

A movement in American Psychology popularized in the 1960s and 1970s, humanism emphasized the realization of the full potential of the self by healthy persons. The movement arose as a reaction against the deterministic and pessimistic approaches of the behaviorist and psychoanalytic camps, which reigned in the field for much of the twentieth century prior. The humanists emphasized human freedom, choice, potential, and self-actualization.

Related Terms

[Humanistic](#); [Paideia](#)

The “humanities” is a term that can be traced all the way back to the ancient Greeks, where it originated as a method of educating youth, known as *paideia*. In antiquity such education centered on seven major subject areas, which consisted of grammar, rhetoric, and logic (known in Roman times as the “trivium”) and geometry, arithmetic, music, and astronomy (referred to as the “quadrivium”). Whereas *paideia* was almost exclusively practical in nature, later these seven fields came to be considered the core of what we now term the *liberal arts*. The first formulation of what later came to be dubbed the humanities can be found in Cicero,

a Roman philosopher and political thinker who lived and wrote in the first century B.C. A prolific scholar and translator of the Greek legacy into Latin, Cicero promoted the notion of the *studia humanitatis*, or “study of all things human,” as a means of achieving the ideals of intellectual and moral perfection ensconced in the strategies of *paideia*.

At the same time, the concept of the humanities per se did not really crystallize until the Renaissance, when it came to connote the totality of the new “humanistic” knowledge that had been recently discovered in the multitude of newly translated ancient texts. This new knowledge at times challenged, and routinely expanded, the medieval worldview, founded largely on the authoritative teachings of the Catholic Church and the opinions of the ancient clerical fathers. Renaissance humanism encompassed not only literature and language studies but as much of scientific knowledge and speculation – whether ancient or contemporary – that was either plausible or feasible at the time. What we now understand as “science” per se was then considered “natural philosophy,” a term that endured up through the nineteenth century. Natural philosophy was not separate from humanistic learning, but an integral branch of it.

It was only with the rise of empirical science in the waning years of the Renaissance, first outlined as a radical new approach to the study of nature and to philosophy itself by the English philosopher Francis Bacon in his *Novum Organon* (1620). Bacon proposed that science should not proceed by deductive syllogism, as it had in the past, but by an “inductive” method of examining a variety of situations or circumstances in which a phenomenon could be observed, then by inferring the nature or behavior of the phenomenon by comparing these situations or circumstances. These now obvious principles became the cornerstone of what today we would deem the “scientific method.”

Because Bacon focused on the practical or worldly outcomes of scientific inquiry, as opposed to their purely theoretical value, his “new organon” inspired the close alliance between scientific discovery and technological

innovation, which laid the groundwork for the industrial revolution over two centuries later. In the wake of the Baconian transformation of the scientific enterprise, the humanities rapidly evolved into a separate domain of study, focusing primarily on history, philosophy, literature, drama, rhetoric, and study of the arts. By the late eighteenth century, the divorce was virtually complete, except in countries at the time that were relatively backward technologically such as Germany, where so-called *Naturwissenschaft* (the speculative “philosophy of nature”) played a significant role in the flowering of what came to be known as “German idealism.”

German scholars, however, were also instrumental throughout the nineteenth century in reviving from the Renaissance the technical study of languages and word origins. This intensive preoccupation led to the rise of the field of linguistics, which from its inception has generally be considered both a science and a discipline within the humanities. Linguistic studies of many non-European and ancient, but nonclassical, sacred texts by these scholars sparked about the same time both the emergence of the so-called higher criticism of the Bible, concerned with the historical rather than the theological meaning of passages from Judeo-Christian Scriptures, and the systematic study of non-Western religions. The latter was known in the nineteenth century as *Religionswissenschaft* (literally, “the science of religion”) and eventually grew into what is now one of the major disciplines in the humanities – “religious studies.”

In addition, the linguistics revolution has had a powerful influence on the humanities in general in the twentieth century. The impact initially was felt in philosophy, which became concerned almost exclusively with problems of language and logic after the First World War. The influence pervaded not only in the English-speaking world, where it dominated what came to be known as “analytical” philosophy, or “language philosophy,” but on the continent of Europe where it left its mark on the movements known as “phenomenology” and “structuralism,” the latter deriving from the school of “structural linguistics” pioneered by the French thinker Ferdinand de

Saussure. By the 1960s, structuralism and its rebellious stepchild “post-structuralism” had begun to make major inroads into literary criticism, which by a decade or so later had colonized most of the humanities. Both structuralism and post-structuralism, which soon came to be identified with the technical strategy of reading texts invented by the French philosopher Jacques Derrida known as *deconstruction*, had no interest in either the historical-critical context, or content, of the humanities as a whole. So-called deconstructive readings of unfamiliar as well as familiar texts were all the rage. They often combined highly arcane and jargon-ridden discourse lifted from post-structuralist theories of meaning and signification with Marxist and other kinds of trendy academic forms of political critique. The popular stereotypes of the new “deconstructionist” humanists promoted in the media and by newly enfranchised conservative critics throughout the 1980s were either that of aging political radicals left over from the 1960s, who had turned their “nihilistic” contempt for the social order into a siege of the genteel traditions of liberal learning, or that of self-indulgent intellectual poseurs who sought to dazzle the public with what was in reality pure nonsense.

The stereotypes were grossly misleading and reflected in huge measure the right-wing, anti-intellectual backlash of the period. But like all stereotypes, there was a kernel of truth in them. Today the general consensus among humanists is that the post-structuralist (or what eventually was referred to as “postmodernist”) revolution in the humanities is over and that in retrospect it did more damage than good to the reputation of the field. Nevertheless, because of the de facto convergence of technical linguistics, Marxist-tinged “materialist” social science, and traditional inquiry into the meaning and values of culture that the deconstructionist movement sealed, the humanities as a result were far more prepared to engage in conversation with the sciences. The English physicist and novelist C.P. Snow’s famous distinction, pronounced in the late 1950s, between the “two cultures” of the science and the humanities had sustained

a dualistic mentality about the nature of knowledge for almost two generations. But at the turn of the millennium, the distinction was finally breaking down. In the past decade, many leading-edge theorists in the humanities have somewhat gingerly sought an alliance between certain seemingly relevant scientific subdisciplines, including sociobiology with its Darwinist emphasis on the random and evolutionary nature of moral values and spiritual ideas and cognitive and neuropsychology with their fresh perspectives on how key problems of mind, historically the province of philosophy, can be investigated. The swift decline in the prestige of Marxist theory as a consequence of the worldwide collapse of communism during the last quarter century has prompted many younger humanities scholars, who yearn for some kind of social legitimacy and broader academic respectability for what they do as a matter of course, to seek out new kinds of partnership with presently fashionable strands of materialist science.

Ironically, it has been this flirtation with those subfields of the sciences that has been used or is currently used to downgrade the importance of or to explain away religious phenomena and religious experiences that have propelled a renewed interest for the humanities in the relationship between science and religion. A century ago, it was the hope that advances in the sciences might serve to sustain rather than undermine common religious assumptions and theological surmises. But today the same interest seems to be motivated by the suspicion that many of the so-called transcendental or semireligious presuppositions of the humanities, particularly the claim that canonical texts, works of art, and ethical reasoning have a peculiar spiritual or irreducible significance in their own right, all add up to something like the Wizard of Oz, who commandeers a grand machinery of pretense and illusion to mystify, if not entertain, the breadth of humanity. Many humanities scholars have come perhaps to secretly see themselves as the little dog Toto, innocently sniffing behind the screen with the hope that they might at least serendipitously reveal the humanities for the hoax that it has always been. Such views in

many cases may be born of a sense of doubt, and low professional self-esteem for which the recent hollowing out of the humanities by Marxist critical theory is largely responsible. But there is also a positive curiosity as to how the religious and spiritual qualities of humanistic thought might be reconciled with new scientific discoveries. What might be considered strong “Manichean” perspective about the irreconcilability of the sciences and the humanities arose in an era when a triumphal scientism had basically made such a rapprochement well-nigh impossible. Snow’s views found a receptive audience among that learned segment of the culture who did not acquiesce in the age of Sputnik to the dogma that scientific and technical advance was the end-all and be-all of human aspiration. But now that the rabid anti-scientism that set in as a response to the Vietnam debacle a decade later has long since run its course, humanities scholars as a rule are far more open to the Renaissance vision of the unity of all knowledge.

Since the humanities historically have always been preoccupied in different ways with the question of the health and integrity of the human “soul,” it is only natural that today it would continue to keep a close eye on what the cognitive and neurosciences tell us, especially about the wonders of the brain and the mysterious production of the phenomenon we call “mind.” From the late nineteenth century up until the mid-twentieth, science by and large had for its own reasons excluded the contributions because of its dubious conviction that conscious processes are nothing more than perturbations of an easily definable material reality. The so-called *mind/brain duality*, first characterized by the French philosopher René Descartes in the 1600s, has propelled the modern prejudice that we must understand thought and cognition either as an “epiphenomenon” of the brain’s machine-like operations or as something entirely independent of the laws and regularities of the material world, which science scrutinizes. Science of course preferred the former approach. Such a “mechanistic” psychology, which reached its high water mark in the radical behaviorism of B.F. Skinner during the

mid to late twentieth century, was founded on the paradigm of material reality as matter in motion originating with Newtonian physics in the early modern era.

Yet, in the wake of Albert Einstein’s theories of relativity and the advent of quantum physics during the last century as well, Newtonian mechanics seemed less and less relevant to the effort to apply scientific method to the study of human cognition. The quantum paradigm of a universe unfolding in accordance with indeterminable and at times incalculable subatomic fluctuations that seem almost “random” has in recent years engendered a suspicion that the brain does not obey iron-clad laws of matter in motion, but can only be comprehended as following similar nondeterministic precedents. What is now known as *quantum mind theory* has evolved from both empirical research and higher-order speculation on the part of such well-respected scientists as David Bohm, Roger Penrose, and Henry Stapp, who argue that known neurological interactions and phase changes in the brain evidence something that is not reducible to these interactions and changes. Bohm calls this irreducible *x* the “implicate order” of the universe. The implicate order is a postulate Bohm offers to explain the feedback loops between the different levels of structural manifestation in what we deem material reality and cognitive and symbolic interventions.

While many scientists during the last quarter century, therefore, have developed models that can accommodate humanistic notions of mind, or the nonmaterial order of things, certain thinkers in the humanities have started to challenge the traditional notion that what they study is purely corporeal. This movement has its roots in the German scholarship of the nineteenth century, which consistently preserved remnants of the Renaissance ideal that the humanities and the sciences comprised an integral synthesis, if not a unity. One of the reasons for this fidelity to the Renaissance prototype is the expansive meaning of German word *Wissenschaft*, which can be translated not only as “science” in the technical sense but as the “pursuit of knowledge”

in the broader sense. German thought has never been bedeviled by Cartesian dualism in the same way that Anglo-Saxon letters have been, perhaps because of this very linguistic discrepancy.

Modern German philosophers for centuries have emphasized the inseparability of the body-world from conscious subjects. The nineteenth-century thinker Wilhelm Dilthey, who located the discipline of the humanities in the historical imagination and its ability to discern the interconnection between material and spiritual factors, and the twentieth-century philosopher Martin Heidegger, whose concept of human existence as *Dasein* implied consciousness as a non-dualistic relationship between subject and world, are examples that come immediately to mind. A third recently influential figure is the French phenomenologist Maurice Merleau-Ponty, whose notion of mind and body not as a disjunction but as what he named a *chiasmus* (in rhetoric, a cross structuring of equally codependent clauses or variables) has had a major impact on contemporary gender studies, cultural studies, and what are known as “body studies.” The German word *Geisteswissenschaft*, commonly translated as “the humanities,” derives from the nearly untranslatable term *Geist*, which can mean “spirit” in the disembodied sense but also the entirety of intellectual capacities and functions. With the decline of post-structuralism in the humanities as an enterprise preoccupied with texts and semantic configurations, the old impulse of *Geisteswissenschaft* has been taken up anew with implicit attention to the latest developments in the somatic, cognitive, and neurosciences.

The French social theorists Bruno Latour and Pierre Bourdieu represent two prominent critics of post-structuralism, who have laid the groundwork for a realignment of the humanities with the sciences. The growing significance of cultural studies, which approaches familiar questions in the humanities with hybrid methodologies drawn from the conventional social sciences, has provided an important context for this realignment. Figures like Latour and Bourdieu can be

considered neither materialists nor “idealists” in the classic sense. Nor have they stuck with the now overworked template of neo-Marxist *social constructivism* that has also been dubbed “cultural Marxism” – the view that the objects of investigation within the humanities are always best interpreted as projections of underlying social formations, whether those be class interests, patterns of social domination, or ethno-cultural competition.

The intermingling of cultural Marxist and post-structuralist rhetoric in the discourse of the humanities throughout the last quarter of this century has created a certain confusion concerning whether the humanities are something special in their own right or a mere extension of the social or linguistic sciences themselves. But these new cultural theorists, taking up where Latour and Bourdieu have left off, who are recognizable, at least on Anglo-American grounds, neither as social scientists nor as “humanists” with the grand, almost Ciceronian connotations that the expression conjures up, have less of an interest in culture as a general anthropological category within a general theory of social organization, behavior, and transformation than as the key to how mind itself is subtly and effectively “embodied.” The exploding science of complexity theory has also had tremendous repercussions for this kind of undertaking.

Edward Slingerland, whose training is in the humanities, has been one of the most vocal advocates of both an embodied science and a new horizon for a scientific humanism. In his *What Science Offers the Humanities* (2008), Slingerland argues that both the humanities and sciences have always confronted a “grounding problem” which they can never resolve without serious cross talk between the two. The older conundrum of embodied mind ultimately boils down to “how ‘symbols in the head’ can connect with things in the world (Slingerland 2008, p. 17).” Slingerland traces the trajectory of evolving theories of how these connections take place from philosophical pragmatism through Jean

Piaget's "genetic psychology" to the subdivisions of cognitive science known as "mental space," "conceptual metaphor," or "conceptual blending" theory. These theories do not regard cognitive processes, including the symbolic imagination, either as an autonomous series of events that adhere to their own internal logic, as structuralism and post-structuralism might presume, or as what the philosopher Gilbert Ryle once called the "category mistake" of confusing mind with the material organization of the brain. Instead they look upon them as discrete types of dynamic and fluctuating spatial mappings, which depend on changes in the physical location, orientation, agency, goal directedness, and movement of human bodies in their environments. Cartesian "parallelism" is therefore replaced with a sophisticated kind of interactionism. Linguistic and cultural differences, including varying worldviews among human groups, can be thus seen at the same time as unique in some sense and also as the immediate or long-term consequence of distinctive environmental circumstances.

Material culture thus becomes as important as its symbolic counterpart. Slingerland himself gives special consideration to Jared Diamond's exploration of what might be dubbed "cognitive geography" in his award-winning book *Germes, Guns, and Steel: The Fate of Human Societies*, published in 1997. Diamond argues that such seemingly minor factors, as whether certain human beings in certain parts of the world domesticated animals early or whether they lived in relative isolation from other societies, over time have had an enormous influence on how cultures developed, what symbolic productions they retained or were responsible for, which conceptual metaphors they used, whether they prospered, and how they fare in the political and economic pecking orders of civilization. Diamond's theories are neither reductionist nor deterministic in the strict sense, but go a long way toward showing how cultural diversity and environmental variation interact closely and fatefully with cognitive efforts at explaining and living in

harmony with the world around us. Slingerland, a Sinologist and Chinese linguist by training, offers his own distinctive theory of how East Asian culture and thought unfolded through what he refers to as the "vertical integration" of cultural, historical, and religious studies with cognitive psychology and material geography.

Prior to the post-structuralist revolution, the humanities were more interested in celebrating the way in which their field served as a gatekeeper to those relatively privileged forms of symbolic communication that fostered appreciation of what was most distinctively "human." Humanities scholars often relished the "impractical" nature of their field, following the hierarchy of intellectual values and pursuits defined in the ancient world by Aristotle and revered as the mainstay of the truly contemplative life. Post-structuralism and cultural Marxism sought, however, to stress the humanities as an avant-garde strategy of sophisticated theory and praxis concentrating on a sustained critique of power relationships and ideological formations with the aim of engendering, or at least abetting, meaningful social transformation.

The new "embodied humanities" has more complex and not so obvious goals, insofar as it appears to have a clear idea for both upgrading the social prestige and intellectual relevance of the field while offering it up as an occasional handmaiden to the medical, social service, and helping professions. Thus, the general venture of practical and professional ethics has become a guiding thread for the new generation of humanists. While scientists ask the question of "what is going on," humanities scholars pose the accompanying query: "why is it important to know?" The humanities continue to propose larger questions or, as Derrida puts it, the "question of the question," involving the meaning of life and death in ways the sciences cannot or should not. But it has begun to recognize that these questions cannot really be addressed without the knowledge supplied by the sciences themselves. The ultimate question of what is real, or "what is the meaning of Being" in Heidegger's

argot, is the kind of *metaquestion* that neither the sciences nor humanities can answer on their own. On the contrary, they can only begin to approach such a metaquestion through close collaboration, mutual respect, and fine-tuning of their respective argots and vocabularies in such a manner that the Renaissance vision of a convergence of the totality of knowledge pathways that ultimately give us a glimpse of the *sumum bonum*, the highest good for humanity itself.

Hyperstructures

Victor Norris

Department of Biology, University of Rouen,
Mont Saint Aignan, France

Many functions in bacteria are performed by large structures (known as *hyperstructures* (Norris et al. 1999), *modules* (Hartwell et al. 1999), *metabolons* (Srere 1987), *SOWAWN* (*self-organizing-when-ever-and-where-ever-needed machines*) *machines* (Ji 2012), etc.) in which small molecules, macromolecules, and ions are physically associated (Norris et al. 2007). In the case of *Escherichia coli*, *Bacillus subtilis*, *Caulobacter crescentus*, and other model bacteria, examples of such *hyperstructures* include: the array of chemotaxis-specific receptors (Tar, Tsr, Trg, Tap, and Aer); dynamic, coupled transcription-translation and transcription-translation-insertion (transertion) *hyperstructures* comprising active RNA polymerases and ribosomes along with the nascent mRNAs and nascent proteins and indeed the highly expressed genes themselves; the cytoskeletal filaments MreB, CreS, and FtsZ; filaments of elongation factor EF-Tu; filaments of the degradosome (comprising RNA helicase B, polynucleotide phosphorylase and enolase) (Taghbalout and Rothfield 2007); *metabolons* of glycolytic enzymes (Velot et al. 1997); foci of the enzymes E1 of the phosphoenolpyruvate: sugar phosphotransferase system; clusters of secretion enzymes such as SecA; nucleofilaments of recombination enzymes such as RecA; the cell division machinery (comprising a lipid domain and proteins such as FtsZ, FtsA, FtsI, FtsK, and AmiC); the DNA replication factory (comprising enzymes such as PolC, DnaB, DnaG, and DnaE as well as enzymes responsible for the synthesis of precursors such as ribonucleoside diphosphate reductase); cellulosomes (massive assemblies of enzymes on the outside of the bacterium that digest molecules such as cellulose) and polycellulosomes. *Ambiquitous* enzymes can occupy two different positions in the cell

Human-Machine Organism

- [Cyborgs](#)

(Nemat-Gorgani and Wilson 1980) and some hyperstructures depend on such enzymes and are functioning-dependent *structures* that assemble only when functioning and that disassemble when no longer functioning (Thellier et al. 2006). Other hyperstructures are equilibrium or quasi-equilibrium structures that remain even in the absence of a flow of energy or nutrients. It has been proposed that hyperstructures constitute a level of organization intermediate between macromolecules and the bacterial cell itself (Norris et al. 2007). Communication between hyperstructures would then take the form of changes in: DNA supercoiling, ion condensation on charged filaments, signaling molecules, water structures, and distribution of membrane domains. At this intermediate level of organization, hyperstructures would control the phenotype and, in particular, the bifurcations that occur, as during the cell cycle, so that events take place in the right place, at the right time and in the right order. Exploration of the hyperstructure concept may also prove useful for understanding eukaryotic cells and, for example, interactions between hyperstructures have also been invoked to explain the structure and functioning of mitochondria and to explain the existence of mitochondrial DNA (Trinei et al. 2004).

Description

In a report on hypnosis for the British Psychological Society, hypnosis was defined as:

An interaction between one person, the “hypnotist,” and another person or other people, the “subject” or “subjects.” In this interaction, the hypnotist attempts to influence the subjects’ perceptions, feelings, thinking, and behavior by asking them to concentrate on ideas and images that may evoke the intended effects. The verbal communications that the hypnotist uses to achieve these effects are termed “suggestions” (Heap et al. 2004). Autosuggestions refer to suggestions that are self-administered, while the “classic suggestion effect” entails that responses elicited by suggestions are experienced as involuntary and effortless (Heap et al. 2004).

Verbal suggestions to relax and focus attention, typically administered in a standardized way as a “formal induction procedure,” are used to establish a hypnotic state or “trance.” In keeping with the content of commonly used suggestions in the induction procedure, the hypnotic trance is characterized by attentional absorption, disattention to extraneous stimuli, and relaxation. However, “active-alert” inductions conducted during physically active states such as riding a stationary bicycle indicate that suggestions of physical relaxation per se are not necessary for a state of absorption and suggestibility to be established (Heap et al. 2004). Hypnotic trance is similar to other more everyday states of absorption, such as immersion in reading, a film, or music, but the focus of attention is directed by the content of the relevant suggestion – for example, sensory foci (a spot on the wall or the voice of the hypnotist) or imagery (walking down steps into a garden), while the “depth” (intensity) of the experience is often profound in highly suggestible individuals.

A variety of scales have been developed to measure individual responsiveness to suggestions, such as the Harvard Group Scale of Hypnotic Susceptibility (Shor and Orne 1962). These scales generally include a hypnotic induction followed by test suggestions and an assessment of the subject’s response to each. “Hypnotisability” or “hypnotic suggestibility” is typically defined as the number of suggestions that an individual responds to on a standard scale of this type. A distinction is drawn between

different types of suggestion – ideomotor suggestions involve automatic movements (e.g., arm levitation), challenge suggestions involve an inability to complete an action when instructed to do so (e.g., eye opening), while cognitive suggestions involve significant alterations in experience (e.g., hallucinations, amnesia, anesthesia). Most suggestions are intended to be effective at the time of their administration, but posthypnotic suggestions influence behavior at a later time (e.g., the suggestion in the Harvard scale that the participant will touch their ankle when hearing a tapping sound but will forget having been given the suggestion).

Induction of the hypnotic state appears to facilitate responses to further suggestions (e.g., of arm levitation), although some individuals respond to the same suggestions without a formal induction procedure (Nash and Barnier 2008). Nevertheless, the associations and expectancies built up around the term “hypnosis” in societies familiar with the term appear to be suggestive in their own right. For example, labeling an induction procedure as “relaxation” produces a modest increase in suggestibility, while labeling the same procedure as “hypnosis” significantly increases suggestibility (Nash and Barnier 2008). This suggests that the term and concept of “hypnosis” should be regarded as a “cultural representation” with its own history and cognitive effects (Deeley 2006).

At the present time, hypnosis is principally employed in the treatment of medical and psychological disorders and in psychological research (Nash and Barnier 2008). Intrinsic hypnosis research investigates the nature of the hypnotic state or trance. By contrast, instrumental hypnosis research employs suggestions to create experimental models of phenomena of psychological interest, such as analgesia, hallucinations, or limb paralysis (Nash and Barnier 2008).

Different theories of hypnosis or suggested effects can be broadly labeled as either “special state” or “sociocognitive” theories. “Special state” (or “state”) theories consider responsiveness to suggestions to be explained by the distinctive properties of the altered state of

consciousness, hypnotic condition, or “trance” produced by the induction procedure. Recent “state” theories based on neuropsychological models of executive function (such as “dissociated control” or “neodissociation” theories) emphasize the role of “high-level” processes in the control of action, particularly in circumstances where novel, complex, or flexible responses are required. Executive processes include attention, working memory, planning, response selection, and inhibition, while their engagement in the generation of controlled action is typically accompanied by awareness and a sense of voluntary control. The key claim is that hypnosis involves an inhibition of executive function and corresponding overreliance on situational cues (particularly those conveyed by suggestions) for the control of behavior. The inhibition of high-level executive control is held to account for the lack of awareness or involuntariness of suggested effects (with theories differing as to how or in what respects this occurs). By contrast, sociocognitive theories reject the idea that a special state of executive inhibition is required for suggested effects to be generated, citing evidence of hypnotic responding in the absence of trance induction in some high hypnotizables. The broad thrust of sociocognitive approaches is to emphasize the role of normal psychological processes and influences to account for hypnotic responding, such as imagination, motivation, expectancy, role playing, compliance, and attributions which reframe the active contribution of the subject to the suggested effects to diminish the sense of agency in their generation. These processes are also considered relevant to the very establishment of the “hypnotic state” itself in response to the suggestions in the induction procedure, with increase in responding to suggestions after induction attributed to changes in expectancy and motivation rather than a uniquely altered state of consciousness involving executive inhibition (Heap et al. 2004; Nash and Barnier 2008).

The history of hypnosis is relevant to understanding current debates about the nature of hypnosis, as well as the relationships between hypnosis and religions.

Firstly, a distinction can be drawn between the use of suggestions or suggestive processes to influence experience and behavior and theories of hypnosis. Indeed, individuals can effectively employ what from the perspective of hypnosis theory and practice are suggestions without interpreting them as such. For example, a report from 1775 about the Austrian exorcist Father Johann Joseph Gassner (1727–1729) describes how he asked a nun suspected of possession whether she agreed that anything he should order would happen. She agreed, and then, he ordered any possessing spirit to manifest itself – which it did (Ellenberger 1994). Gassner’s writings make it clear that he believed these effects were supernaturally caused, but his practice resembles nonreligious applications of hypnosis in which a subject hands over executive control to a special agent (the “hypnotist”) and conforms their behavior to expectations established within the hypnotic context (Oakley 1999). Similarly, Gassner’s contemporary Anton Mesmer (1734–1815) developed many suggestive techniques for the purpose of healing, such as passes of the hand over the patient’s body to produce “crises” (swooning, convulsions, shaking, crying, hysterical laughter, among other signs), followed by a stupor. However, Mesmer interpreted these effects in terms of his quasi-physical theory of “animal magnetism.” He even believed that Gassner had unwittingly used animal magnetism to effect his cures, confiding to an associate that “Gassner possessed magnetism to an extraordinary degree and his own powers were not so great” (Ellenberger 1994). Successors such as Marquis de Puysegur (1751–1825) adopted and developed Mesmer’s techniques, while rejecting the quasi-physical theory of animal magnetism in favor of psychological theories which are the precursors of contemporary theories of hypnosis (Ellenberger 1994). Puysegur dispensed with the dramatic crises of Mesmer, producing a more quiescent “perfect crisis” or “artificial somnambulism” comprising apparent wakefulness, obedience to the commands of the magnetizer, and then amnesia after being “disenchanted” by kissing a tree (Ellenberger 1994). The wakefulness and obedience (suggestibility) of “artificial

somnambulism” are prototypes of subsequent hypnotic conditions, although the induction and deinduction techniques, presence of subsequent amnesia, and interpretations of the condition have changed with time. For example, Abbe de Faria (1756–1819) produced the related condition of “lucid sleep” with the command “sleep!” rather than mesmeric passes (Ellenberger 1994). The term “hypnosis” was coined in 1832 by James Braid (1795–1860), who viewed it as a distinct physiological state characterized by fixed stare, relaxation, suppressed breathing, and fixed attention to the words of the hypnotist (Heap et al. 2004). Despite these and subsequent changes in both the theories and practices of mesmerism and hypnosis, their advent brought increasing awareness of the existence and possibilities of suggestions, to the extent that in contemporary practice, suggestions are explicitly designed to produce specific effects – for example, as part of psychological treatment or research (Nash and Barnier 2008). Further, historical variations in the hypnotic condition illustrate the extent to which it is constituted by specific suggestions which vary with the hypnotist and the “school” to which they belong, in conjunction with the social learning and expectancies of the subject. Nevertheless, the responses elicited by suggestions in these diverse hypnotic conditions are experienced as involuntary, effortless, and realistic in keeping with the “classic suggestion effect.”

Familiarity with religious practices and pre-suppositions appears to have influenced developments in hypnosis theory and practice in different ways in the late eighteenth and throughout the nineteenth centuries. For example, Mesmer’s “crisis” recalled the convulsive crisis attending the onset of possession (Ellenberger 1994). Mesmerism and hypnosis were also often conceived as giving access to special knowledge in “lucid” subjects – such as the diagnosis and cure of illnesses and clairvoyance – resembling the disclosures previously called forth from the interrogation of possessing demons. The special knowledge made possible through mesmerism and hypnosis inspired an “experimental metaphysics” among German Romantics, in which

extrasensory perception; knowledge of the past, future, and “world soul”; and other exalted noetic states could be attained (Ellenberger 1994). The boundaries between hypnosis, spiritualism, mysticism, hysteria, and possession were – in some cases – very fluid. For example, the German physician Justinius Kerner (1786–1862) considered possession a “demonic-magnetic disease” and treated it with a mixture of exorcism and magnetism (Ellenberger 1994). The appropriation of hypnosis or suggestive techniques by new religious or spiritual movements and view that it gives access to special knowledge (such as knowledge of past lives) has continued to the present day.

An alternative trajectory saw hypnosis employed as a secular method of medical treatment and object of scientific inquiry. This trend was reinforced by the rise of positivism and scientific rationalism in the mid-nineteenth century and forms the background to the contemporary scientific study and clinical applications of hypnosis (Ellenberger 1994). Surgery under magnetic anesthesia was employed by Recamier as early as 1821 (Ellenberger 1994). The neurologist Jean Martin Charcot (1825–1893) and the philosopher and psychiatrist Pierre Janet (1859–1947) used hypnosis as a way of understanding and treating hysteria (quasi-neurological signs and symptoms in the absence of tissue pathology that could adequately explain them) (Bell et al. 2010). In particular, it was noted how hysterical (dissociative) symptoms such as paralysis, amnesia, anesthesia, involuntary movements, convulsions, and hallucinations could be produced by suggestions, while suggestions could also be used to remove hysterical symptoms. Charcot and Janet considered both hysteria and hypnotic effects to result from unconscious “fixed ideas” that were the result of (auto)suggestions, with Janet postulating “narrowing of the field of consciousness” as the basis of dissociation of normally integrated cognitive functions in both hysteria and hypnosis (Ellenberger 1994). Drawing on cognitive neuroscience evidence of shared neural mechanisms underlying dissociative and suggested phenomena, Oakley similarly proposed that both dissociative and hypnotic

phenomena belong to a supertype of suggestive processes – in other words, dissociative phenomena are generated by processes of autosuggestion that resemble the processes producing hypnotic phenomena (which are usually allo-suggestive, but can be auto) (Oakley 1999). At a neural level, there is increasing evidence that symptoms in both hysteria (clinical dissociation) and their suggested analogues in hypnosis are associated with increased activity in overlapping prefrontal cortical regions, suggesting that intervention by the executive system in both automatic and voluntary cognitive processing is common to both hysteria and hypnosis. However, comparable brain regions involved in motivation and processing stimuli related to the self may also be engaged (Bell et al. 2010).

Similarities between features of possession trance (identity change with or without amnesia and other dissociative symptoms); sense of altered identity in dissociative identity disorder and method acting, respectively; and suggested effects of identity change, amnesia, and other features in high hypnotizables have led to the proposal that suggestive-dissociative processes may also underlie many instances of possession (Deeley 2003; Taves 2006). By extension, suggestions in high hypnotizables are likely to be relevant to modeling cognitive and neural mechanisms enabling other culturally or religiously recognized forms of experience and behavior – in particular, any alterations in the control, awareness, or ownership of thought, perception, speech, and actions (as in mediumship, prophecy, or other types of inspired speech or writing); states of profound attentional focus and psychosomatic quiescence such as absorptions (Skt. *dhyanas*, Pali. *jhanas*) in concentrative meditation; anesthesia in ascetic mortifications or ritual ordeals such as self-piercing; and vivid visionary experience such as shamanic spirit journeys or tantric visualizations.

Nevertheless, this proposal does not entail that possession or other forms of religious experience are nothing but hypnosis or even due to hypnosis. Rather, the claim is that similar alterations in experience and behavior encountered in distinct contexts (clinicopathological, religious, artistic,

hypnotic) may share the efficient causal mechanisms of suggestive-dissociative processes at a cognitive and neural level. One category (such as clinical dissociation, possession, or hypnosis) cannot be reduced to another because all acquire context- and tradition-specific extended meanings, values, and purposes by virtue of their distinctive histories. Indeed, the meanings, expectancies, and differing local interpretive frameworks of terms such as “possession,” “hysteria,” and “hypnosis” are likely to powerfully shape and differentiate the phenomena in question. For example, most suggestions employed in hypnotic contexts involve ideas that temporarily contravene ideas of reality and would otherwise be regarded as imaginary or false by both hypnotist and subject (such as a suggestion of an arm rising because it is attached to a helium balloon). By contrast, arm levitation in the case of possession would typically be attributed to the action of a truly existent agent such as a god, spirit, or demon, with ramified conceptual, affective, and practical associations that are widely shared by a relevant social group (Deeley 2004). The presence of strongly held beliefs and authoritative social practices as opposed to temporarily imagined scenarios may affect the threshold for experiencing the respective phenomena, quite apart from differences in their attributed significance (Deeley 2003). Similarly, in modern practice, suggestions in hypnosis are predominantly verbal in form, whereas with exceptions (such as the case of Gassner noted above), cues engaging suggestive-dissociative processes in possession trance are more likely to be nonverbal (such as the musical motto signifying the descent of a specific possessing agent in possession rituals, quite apart from expectancies engaged by the overall context). Hence, cognitive or social neuroscience approaches to suggestive-dissociative processes require a more extensive analysis of the prior enculturation and range of cues and contexts that inculcate and/or elicit them (Seligman and Kirmayer 2008). This will involve a continuing dialogue with anthropological and other perspectives on how the forms of experience made possible by suggestive-dissociative processes are interpreted and affect human lives.

Identity (Philosophy of Mind)

Gregory Peterson

Department of Philosophy and Religion, South
Dakota State University, Brookings, SD, USA

In philosophy of mind, a major issue is the relation of mind and brain, with early theories

suggesting that mind and brain are identical. This early identity theory quickly encountered criticism, as every brain is slightly different, and human brains are different from animal brains. If having a pain or computing an addition operation is just a particular kind of brain event, then identity theory was committed to the view that it must be the exact same brain event in every individual. Identity theorists thus argued for what came to be called type-type identity, that is, for every type of mental event there is one and only one type of physical event. An approach to philosophy of mind known as philosophical functionalism came to reject this thesis, arguing instead for token-token identity, which denies that it is necessarily the case that for each type of mental event there is one and only one type of physical event, arguing instead that for any individual mental event (a mental “token”), there is a physical token or set of tokens that are said to realize the mental token. On this view, having a pain always is realized physically, but having a pain can be realized differently in different organisms. Thus, the affirmation of token-identity and the denial of type-identity gives rise to multiple realizability, the view that any given type of mental property can be realized by different physical systems. Multiple realizability arguments have been particularly important in debates about the possibility of artificial intelligence.

Ihsan (good personal conduct), the third aspect of the Islamic creed (first is Islam itself, second is Iman) is described as the act of worshipping Allah as if you see Him, knowing that even if you do not see Him, He sees you. This goes much beyond the ritual prayers, and every good action performed by a believer is seen as an act of worship. This is commonly expressed by Muslims as doing what is pleasing to Allah, who is present, ever watchful.

Etymology

The Greek and Latin terms for imagination reveal that imagination, from the beginning of Western thought, has been conceived as a kind of secondary, internal perception or sight. The Greek word *phantasia* is derived from *phainesthai*, meaning “to make oneself visible or seen,” and the underlying assumption seems to be that what makes itself seen through the imagination is something akin to but nonetheless different from sense perceptions. According to Aristotle (384–322), imagination makes images or representations appear, and these images (*phantasmata*) “are similar to objects perceived except that they are without matter” (432a9–10). Aristotle even suggests that *phantasia* (imagination) ultimately is derived from *pháōs* (light) (429a3–4), since nothing, in Aristotle’s view, can appear to the perceiving mind without light. Thus, on this account, imagination is, metaphorically speaking, an internal light that makes mental images appear.

The Latin correlates to *phantasia* and *phantasma* are *imaginatio* and *imago*. These terms emphasize stronger than their Greek counterparts the visual, image-making character of the imagination: the mind is like a screen on which the imagination is able to “paint” its images.

In everyday discourse imagination is often used psychologically to describe the mind of either a particularly innovative or delusional human being, that is, in the most extreme cases, the artist and the madman. Accordingly, there exists a certain ambiguity in ordinary talk about imagination/fantasy. On the one hand,

imagination refers to originality and outstanding inventiveness (i.e., to be imaginative and fantastic), and, on the other hand, it refers to various pathologies of the mind (i.e., “it is only in his imagination”). In both cases, however, imagination is supposed to be a subjective and somewhat excessive phenomenon of no particular importance in the practical life of ordinary people.

History

From antiquity to the enlightenment, the dominant theories of imagination in Western thought have stressed the essentially imitative and reproductive nature of the imagination (Kearney 1988). As a power only capable of imitation, the imagination was regarded as inferior to other powers of the mind, especially those of reason and perception. The implicit danger of any act of imitation is, of course, that it opens up the possibility of serious misrepresentation and distortion of the original (i.e., ideas or sense perceptions) that is imitated. Consequently, the imagination was treated with considerable suspicion by philosophers and theologians alike.

The basic philosophical and theological suspicion of imagination concerns the imagination’s ability to distort reality and trick reason into attending false beliefs. For the main part of the thinkers of both Platonic and Aristotelian orientation, imagination must be controlled by and subdued the judgment of reason, for only through the exercise and cultivation of reason, philosophy (science) will be able to lead us toward truth and trustworthy grasp of reality. In relation to this endeavor, imagination is either unnecessary or, at its worst, a direct threat.

Although theories of imagination seem somewhat varied in the seventeenth and eighteenth centuries (Engell 1981), the enlightenment generally continued the suspicious attitude toward imagination and mental images (Daston 2005, 17 ff.). However, the enlightenment and early romanticism also witnessed two epoch-making shifts in the philosophical appraisal of imagination:

(a) As this period celebrates rationality, autonomy, and freedom as the chief expressions of

human dignity, humans are beginning to be regarded as masters over nature and history and capable of controlling their own fate (Soulen and Woodhead 2006, 8 ff.). This turn toward human potentiality is reflected in the emerging romantic notion of the creative imagination, transforming, as it were, the previously held view that imagination was essentially mimetic and reproductive. Simultaneously, the skepticism of the enlightenment toward imagination was gradually replaced by the romantics’ affirmation of creative imagination as humanity’s most exalted power. S. T. Coleridge (1772–1834) even turns the imagination into a theological concept regarding it as a repetition in the human mind of the divine act of creation (Coleridge 1817, 304 f.). In romanticism, science, art, and religious insight is generally interpreted as expressions of true genius, and imagination, thus, becomes the human locus of divine inspiration and epiphany.

Several modern philosophical theories of imagination are deeply imbedded in this romantic tradition of creative imagination, although the theological and epiphanic associations are left out. In Jean-Paul Sartre’s (1905–1980) existential philosophy, imagination is closely related to human freedom. Freedom is the ability to negate reality, and, according to Sartre, this is exactly what the act of imagining does. It replaces reality with imaginings of something that are not real (Sartre 1940). The hermeneutical philosopher Paul Ricoeur (1913–2005) stresses the linguistic aspect of imagination relating it, as it were, to poetic discourse and the creation of new meaning (“semantic innovation”) through innovative use of metaphor (Ricoeur 1975). Finally, the notion of creative imagination reaches its strongest expression in the philosophy of Greco-French philosopher and psychoanalyst Cornelius Castoriadis’ (1922–1997) concept of “radical imagination.” According to Castoriadis, the imagination is radically creative and as such capable of creating new forms “*ex nihilo*,” “out of nothing” (Castoriadis 2007).

(b) During the period of enlightenment and romanticism, the imagination also undergoes

a change from a one- to a multidimensional concept. The multidimensionality of imagination finds expression in many different ways. The German psychologist Johan Tetens (1736–1807), for instance, distinguishes between perceptive, associative, and creative functions of the imagination (Engell 1981, 118 ff.). Immanuel Kant (1724–1804), whose influence in these matters is unprecedented, understands imagination (*Einbildungskraft*) as both an empirical and transcendental faculty, and he operates with a further distinction between “reproductive” and “productive” functions of imagination. Coleridge, for his part, reinforces and widens the Kantian concept of imagination as he distinguishes between “primary imagination” (creation of ordered perceptions), “secondary imagination” (dissolution of perceptions in order to recreate them through works of art), and “fancy” (mechanical association of ideas) (Barth 2001).

At least two consequences follow from the multidimensionality of imagination. First and foremost, these developments within the philosophy of imagination imply an increased theoretical complexity and a more nuanced approach toward imaginative phenomena in general. Secondly, imagination is no longer seen simply as the mind’s ability to make mental images/representations appear. Although the mental and representational aspect of imagination is still relevant, not least in phenomenology and philosophy of mind, other dimensions and functions of the imagination come to the fore, e.g., creative, social, artistic, critical, etc., which cannot be explained within a merely mentalistic paradigm of reproductive imagination (cf. Robinson and Rundell 1994).

Imagination in Science and Religion

The question of the use and importance of imagination in science and religion is very complicated and can be addressed in many ways. For the sake of systematic clarity, the issue will be discussed under three headings:

- (a) Imagination has no role to play in neither science nor religion. Generally, scientific and religious thinkers have been suspicious of any use of imagination in relation to human attempts to comprehend objective reality and/or religious truths. As earlier noted, the prevailing assumption of imagination in Western thought has been that it belongs to the domain of the unreal, and since both science and religion claimed to reveal the fundamental truths about reality, none of them seemed able to make any theoretical use of the imagination. In science, the suspicion of imagination seems to be based on a fundamental distinction between “fact” and “artifact,” the former understood as the objective parts of reality, that which is “given by nature” (Daston 2005, 18 f.), and the latter understood as that which is made by human art, something invented, and in this sense not related to true discovery. In order “to let nature speak for itself” (Daston 2005, 28), and in order to salvage the epistemic objectivity of scientific method, any influence of human art and imagination must be excluded. Another risk of letting imagination play a role in science is that it could easily lead to pseudoscience, e.g., astrology, alchemy, and magic.

The religious suspicion of imagination closely resembles the scientific one. In Medieval rational theology, reason or intellect is understood as the only organ capable of truly comprehending the eternal and immutable ideas residing in the mind of God (Miner 2004, 7 ff.). Since imagination is closely related to sensation, any use of it will only lead to appreciation of the sensible world and, ultimately, to idolatry – the religious equivalent of pseudoscience. Theology of revelation maintains that human knowledge of God is not accomplished through the exercise of reason but depends entirely on God’s self-revelation. Since human nature is corrupted by sin, any use of religious imagination will only undermine the trustworthiness of God’s revelation. The “demythologization program” of German theologian Rudolf Bultmann (1884–1976) can be seen as an example of such an attempt to secure divine

self-revelation from the contamination of human imagination.

- (b) Imagination is essential to religion, but plays no role in science. This position is intrinsic to the nineteenth century critique of religion of which Ludwig Feuerbach (1804–1872) is an evident representative (Feuerbach 1841). According to Feuerbach’s “projection theory of religion” (Harvey 1995, 229 ff.), the fundamental cause of religion is the imagination. In contrast, science and philosophy use reason in a disciplined manner in an attempt to elucidate the objective nature of reality. Hence, imagination, which Feuerbach understands as the diametrically opposite of reason, reality, and objectivity, plays no part in neither science nor philosophy. In religion, however, imagination is put to the service of human wish fulfillment, that is, a primordial desire to transcend the limits of human subjectivity, and this strong alliance between imagination and emotions may ultimately defeat reason and create illusions, most notably the representation of “God.”
- (c) Imagination plays a central role in both science and religion. This position seems to be widely accepted among contemporary philosophers of religion as well as philosophers of science. It may seem counterintuitive that an enlightenment thinker like Adam Smith (1723–1790) would be able to find any use for imagination in science. However, he did maintain that scientists use “the imagination to give us new insights into the familiar natural world” (Downie 2001, 60). As such, imagination must be seen as playing an important role in scientific discoveries. More recently, Ian Barbour has argued that imagination is necessary in science in relation to the construction of theories and models. Theoretical models, according to Barbour, are “imagined mechanisms or processes postulated in a new domain by analogy with familiar mechanisms or processes” (Barbour 1998, 116). In a similar vein, American philosopher of religion Garrett Green, employing Thomas Kuhn’s (1922–1996) concept of paradigms, argues that

imagination is used in science and religion in much the same way. He defines imagination functionally as “the paradigmatic faculty” (Green 1989, 66) which is used heuristically “to reveal the larger patterns in broad areas of experience that might otherwise remain inaccessible” (Op. cit., 67). Thus, “imagination *is* the taking of paradigms to explore the patterns of the larger world” (Op. cit., 69). In science, paradigms are usually called “theories” or “models,” which are used in the exploration of the patterns of the nonfamiliar world; in religion, a similar function is often performed by normative texts, rituals, and dogmas. So, at least functionally, science and religion are similar practices through which creative imagination attempts to make sense of reality (Barnes 1983, 20).

Imago Dei

Jan-Olav Henriksen

(MF) Norwegian School of Theology, Majorstua, Oslo, Norway

Related Terms

[Image of god \(about the human being\)](#)

Description

Imago Dei is the Latin translation of “*image of God*,” which is the designation of the human being in Genesis 1:27. The original Hebrew text seems to suggest that implied in this designation are features that give the human a similar function like those of memorial stones in ancient Middle East: The presence of such stones was intended to make people remember who the ruler in a given area was. When this symbolic function is given to the human as an initial characteristic of its

creaturely status, its religious meaning is that the human is the species whose presence on Earth shall be a sign of God as the creator and ruler of the universe.

From a theological point of view, *imago Dei* may be interpreted as a designation of the human that has several different functions: It draws a clear line between God and the human, creator and creature; it separates the human as a species with a specific distinction from and over against other living beings, thereby also suggesting the human’s status in creation as privileged; and it offers the human a specific task: To live in such a way that the function of being a sign of God as creator of the universe is maintained. In the Christian tradition, during the interpretations of Jesus Christ in the New Testament, the notion has been given a further theological relevance when Christ is seen as the true image of God (Col 1,15), but this latter level of symbolic meaning has hardly been of any relevance to the science–religion debate. The enduring theological significance of the notion, which also makes it culturally vital and important still, is its ability to offer a powerful way of interpreting the human’s unique relationship with God and within creation. Thus, its point is not to indicate specific inherent human capacities or features such as a sign of being created in the image of God, but to indicate the specific *relation* between humans and God.

History and Context

During the centuries, the historical and contextual background suggested above often seems to have been lost to different interpreters of the Scriptures or has been developed into more one-sided interpretations of what is the specific character of the human being in creation. Accordingly, the history of the interpretation of *imago Dei* is complex. The interpretation of the notion can thus be seen as a reflection of the different understandings of the human that have been prevalent during the different periods in the course of history. In this way, *imago Dei* has served as a notion that mirrors what one in a given period with a given theological or philosophical context

has taken to be the distinct human feature when the human is compared to other species. Often, *imago Dei* has been understood as an indication of the *rational* character of human existence or the human's capacity for *moral* conduct. Sometimes, it has also been interpreted as a way to designate the human's capacity for religion. After the Enlightenment, *imago Dei* has often been understood as a theological synonym to the more secular notion of *human dignity*. This latter interpretation has occasionally included echoes of the emphasis on the rational and moral capacities of humans. Presently, *imago Dei* is often understood in ways that emphasize the relational and the embodied way of being human, this also indicating that humans are best understood as communal and not as individual beings. This also has bearings on how the notion is employed, e.g., in debates about euthanasia. In sum, we can see the interplay of substantial, functional, and relational interpretations of *imago Dei* during the history of its theological articulations.

Relevance for Science-Religion Dialogue

The notion of *imago Dei* has had most impact in Western thinking. Although all the three Abrahamic traditions have (to a larger or smaller degree) adopted this as a way to describe the human (in Islam somehow disputed, though), it is mostly due to its development in the Christian (Western) tradition that the notion has been relevant for the science–religion discourse. One can identify its present relevance for the science–religion dialogue along the following lines:

1. *Human Uniqueness*. From a theological/religious view, *imago Dei* has been a strong point of orientation and motivation for those who want to emphasize human uniqueness compared to other species. In its rude forms, this has been taken as a theological warrant for rejecting forms of evolutionary thought that suggest that humans are bound to the same natural and evolutionary conditions as is every other species. Presently, in the more qualified science–religion discourse, one is aiming at finding ways of interpreting *imago Dei* and is able to uphold this notion's more relational aspect, without denying neither human evolution nor the fact that many previously assumed unique human capacities are also to be found in the primates (including the capacity for morality).
2. *Human Dignity*. The notion of *imago Dei* has been invoked in order to safeguard human dignity. This has been done in confrontation with types of research on humans, embryos, fetuses, the human genome, etc., that is perceived as attempts to instrumentalize or reify humans as material and objects for research without taking into account human dignity, human freedom, and the personal dimension of human existence. The notion of *imago Dei* has also been invoked in order to support restrictive stands on euthanasia.
3. *The Ecological Debate*. The designation of humans as created in the image of God is in Genesis connected with the notion of humans as stewards and rulers of creation. This is interpreted by some as one of the causes of the present ecological crisis (White 1967). Because understanding themselves as *imago Dei* may lead humans to understand themselves as set apart from the rest of creation, this may in turn lead to objectifying and exploiting approaches to nature. *Imago Dei* is in this way interpreted as an expression of *anthropocentrism*. One could, however, according to the above discussion, also see *imago Dei* as a way to express the responsibility that humans have for the whole of creation.
4. *The Debate About Speciesism and Animal Rights*. Because *imago Dei* is a religious notion that is applied uniquely to humans, it has been seen as one of the roots of speciesism: the understanding that humans have a privileged place compared to other species and should be given specific value because they belong to this group of species. Speciesism based on the assumption that humans as *imago Dei* are superior and can discriminate against other species according to their own interests may back the accusation that religiously based attitudes toward nature may lead to morally unjustified practices over against other parts of nature.

Impermanence (Buddhist)

Bhikkhu Anālayo

Center for Buddhist Studies, University of Hamburg, Hamburg, Germany

Related Terms

Anicca (Pāli); *Anitya* (Sanskrit)

Description

Realizing the impermanent nature of all aspects of subjective experience, including the whole world at large, is a key aspect in the development of insight into the true nature of reality according

to early Buddhist thought. The argument advanced to support the idea that impermanence does indeed reflect the true nature of reality and experience is that on close investigation all aspects of experience turn out to be subject to change and alteration. This empirical approach, together with the conclusions drawn from it, places this aspect of Buddhist thought in considerable vicinity to science and scientific methodology.

From an early Buddhist perspective, whatever exists turns out on close inspection to be but a changing process, whether this be the whole world, which according to ancient Indian cosmology undergoes periodical destruction, or the fleeting mind, which introspection shows to be changing every moment. Thus, early Buddhist analysis concludes – contrary to the stipulations made in many a religious tradition – that a permanent entity or self cannot be found anywhere at all (Feer 1884–1898, III 144).

In the early Buddhist scheme of deliverance, progress to awakening requires insight into impermanence as its central basis (► [Awakening](#)). Such awareness of impermanence has quite literally to penetrate into every aspect of experience, seeing that each and every aspect of it has arisen and will pass away.

Comprehensive insight into impermanence then builds up the basis for insight into what Buddhist thought considers the other two characteristics of reality, namely, unsatisfactoriness (► [Dukkha](#)) and not-self (► [Anattā](#)). The dynamic that relates these characteristics to each other proceeds as follows: What has been seen with insight as impermanent is next understood to be unsatisfactory. In fact, the reasoning goes that it is precisely because of its impermanent nature that it cannot yield lasting satisfaction. What is unsatisfactory is then in turn contemplated as being devoid of a self. Again, it is precisely because it is unsatisfactory that it fails to qualify as a self.

In this way, seeing the whole gamut of experience with insight as being invariably subject to impermanence and therefore lacking lasting satisfaction will ensure that what is subjectively experienced as a solid “I” that reaches out to appropriate various objects as “mine” is instead

understood with wisdom as being merely a process, a product of conditions.

The importance of penetrative awareness of impermanence for the development of insight and wisdom receives a highlight in the last instruction that, according to the traditional account, was given by the Buddha to his disciples on the eve of his passing away: “conditioned phenomena are of a nature to vanish, [hence] strive on with diligence” (Carpenter and Rhys Davids 1890–1911, II 156).

The conception of impermanence found in the early Buddhist discourses describes phenomena not only as arising and passing away, but at the same time recognizes that, as long as they remain, change will manifest as an “otherwiseness of that which persists” (Morris and Hardy 1885–1900, I 152). This mode of presentation thus combines change with continuity.

With later developments of Buddhist philosophy, however, the continuity inherent in this conception becomes less evident. This is particular the case with the theory of momentariness. From the perspective of this doctrine, things disappear as soon as they have appeared. Such a radical conception of impermanence results in the difficulty that the evident fact of continuity is not easily explained.

The difference between these two conceptions – the notion of impermanence in early Buddhism and the later theory of momentariness – can be illustrated by contrasting a flickering lamp to the steady flow of a river. In the first case, the light of the lamp is experienced as disappearing as soon as it appears. In the case of the flowing water of a river, an image in fact used in the Buddhist discourses to illustrate the impermanence of life (Morris and Hardy 1885–1900, IV 137), the flow of the water is experienced as a changing continuity. Another example, taken from the realm of music, would be the contrast between “staccato,” unconnected notes, and “legato,” when notes are connected to each other.

The early Buddhist conception of impermanence does not face a problem in explaining continuity, unlike the doctrine of momentariness, since besides arising and disappearance it

recognizes that phenomena do persist for some time, even though this continuity is marked by change. In other words, the early Buddhist dictum that all aspects of experience are changing only implies that they are processes, not that they must necessarily disappear right away.

Another significant aspect of impermanence in early Buddhist thought is its intrinsic relationship to conditionality. According to a succinct summary of the Buddhist doctrine of dependent arising, the chief underlying principle of this doctrine is that “with the arising of this, that arises” and “with the cessation of this, that ceases” (► [Dependent Arising](#)). Thus, what is conditioned is necessarily impermanent, and what is impermanent is certainly conditioned, these two notions being but two sides of the same doctrinal coin.

Contemplation undertaken in accordance with what the early Buddhist analysis reckons a correct vision of existence – namely, seeing its conditioned and impermanent nature – leads on to the insight that existence is unable to yield lasting satisfaction and that it is devoid of any permanent substance or self. Such contemplation is held to purify the mind gradually from various mental obstructions and will eventually issue in awakening to the experience of Nirvāṇa, unique in Buddhist thought for not being considered subject to change.

In Vitro Fertilization, Stem Cell Research and Ethics

Eve Herold

Genetics Policy Institute, Washington, DC, USA

In vitro fertilization (IVF) is a technique of assisted reproduction in which the fertilization of an egg by sperm is achieved outside the body. Couples seeking IVF treatments may be experiencing either male or female infertility, but is often utilized when the female produces normal eggs (oocytes) but the eggs cannot travel to the uterus due to damaged fallopian tubes. The technique was pioneered in the 1970s by Robert Edwards and Patrick Steptoe in England. Since then, over three million “test tube babies” have been born throughout the world using IVF techniques.

To perform IVF, one must have viable spermatozoa and healthy eggs at a precise stage of maturity – a fleeting condition for the egg that lasts only a matter of hours. To increase the odds of conception, women undergoing IVF take drugs that cause ovarian hyperstimulation, which causes the ovaries to produce larger-than-normal numbers of eggs. In normal reproduction, these eggs would travel through the fallopian tubes and, if fertilized, possibly attach to the uterine wall and establish a pregnancy. However, in IVF, these eggs are retrieved from the surface of the ovaries via laparoscopy

(a less invasive technique than standard surgery) and placed in a lab dish containing culture medium. The oocytes are carefully observed in order to establish the optimum stage of maturation, and then spermatozoa are introduced to the lab dish. About 40 h later, it can be determined whether fertilization has taken place and if so, the fertilized egg(s) is transferred to the uterus in the hope that it will attach to the uterine wall, develop a placenta, and thereby establish a pregnancy.

Because of a relatively low success rate of embryo transfers (currently about 10–20 %, although some fertility clinics claim up to 40 % success rates) it is routine for doctors to transfer several fertilized eggs (embryos) to the uterus at one time in the hope that one or two will result in a normal pregnancy. Sometimes the result is a multiple pregnancy with very large numbers of embryos beginning to develop. This has led to some couples becoming parents to sextuplets and even septuplets, but in most cases, selective abortion is performed to preserve the health of the mother and increase the chances of remaining embryos thriving. In addition, some embryos created this way are never transferred to the uterus because of chromosomal abnormalities, a failure to divide, and other reasons. Such embryos are cryopreserved (frozen at a very low temperature) until the egg and sperm donors decide upon their disposition. The overall low success rate of IVF means that significantly more embryos will be created than will ever result in a pregnancy or a live birth. Consequently, it is common for couples undergoing IVF treatments to complete their family-building goals and have several embryos left over. As a result, it is estimated that there are approximately 400,000 cryopreserved embryos in the USA alone.

The disposition of left-over embryos can include: (1) the couple could decide to transfer them at a later date, leaving the possibility open for another pregnancy; (2) the embryos could be donated to other couples who wish to use them for reproductive purposes; (3) they can be disposed of as medical waste; and (4) they can be donated for scientific research, including human embryonic stem cell research. So far the

most common disposition of left-over embryos is eventually option number three (disposal). Option number one is rarely chosen because most couples undergoing assisted reproduction not only want to have their own genetic children, they want to limit the number of children they have. The second option, donation to other couples, is very rarely chosen, and represents less than one percent of all the frozen embryos currently being preserved by IVF clinics. Reasons that are often cited include the fact that donor couples are reluctant to have their genetic children raised by others, and the fact that parents who are able to have their own genetic children lack the incentive to “adopt” another couple’s offspring. Donation of embryos to research is chosen in a significant number of cases when offered to couples.

It’s important to note that the options for the dispensation of left-over embryos is generally spelled out in a contractual agreement between egg and sperm donors and the fertility clinic providing treatments. In the United States at least, clinics sometimes agree to maintain embryos in their frozen state for 5 years (for a fee of about \$2,000 per year), while the donors make up their minds about what they would like to do with them. Some clinics require a decision by the donors after 5 years, and some have a policy of never disposing of embryos; however, a study reported in 2005 found that over 80 % of fertility clinics routinely dispose of unused embryos. However, the number of frozen embryos is not expected to diminish because new couples are continuously entering the IVF process, creating multiple embryos, and transferring only some of them.

In vitro fertilization practices have been ethically controversial since the first test-tube baby was born in 1980, and the issue began to receive even more attention after the first human embryonic stem cells were isolated from IVF-created embryos in 1998. This development opened the door to the possibility of scientists using excess IVF embryos in research aimed at utilizing the pluripotent stem cells taken from 4- to 7-day-old embryos (blastocysts) to create cures for cell-based diseases.

Pluripotent stem cells contain the genetic blueprint for the entire human body and are able to give rise to any cell type that may be needed to replace dead or diseased cells in a large array of diseases and injuries. This means that specific tissues and organs can be grown in the lab and transplanted into patients, with the hope of restoring lost or impaired functions. Pluripotent cells that contain genetic mutations for disease can also be used to study the genesis of certain diseases from their earliest beginnings. Many scientists hope to be able to clone embryonic stem cells from the cells of patients who have genetic diseases, to provide human disease-carrying cell populations that can be used in the search for new drugs and other treatments. Even without the extra step of cloning, the ability to grow large numbers of many different human cell types (from embryos) in the lab is considered by scientists to be one of the most important biomedical advancements of the twenty-first century. It is expected that the study of stem cells and the differentiated cells they give rise to will dramatically advance the understanding of human development and biology.

Because of their proven pluripotency and their robust ability to proliferate indefinitely in the lab, the cells obtained from the 4- to 7-day-old blastocyst are considered the “gold standard” of stem cells. Other types of stem cells exist, such as adult stem cells (taken from the fully developed human body) and gestational stem cells (taken from umbilical cord blood and amniotic fluid). These cell types have not been shown to be as versatile or as robust as embryonic stem cells, but they nevertheless can provide certain targeted therapies, such as the rejuvenation of the immune system following chemotherapy, or to cure blood diseases such as leukemia. Another advantage to using embryonic stem cells is their availability in the above-mentioned frozen embryos that are not slated for reproductive use. Many embryos deemed not suitable for transfer to the womb (estimated as approximately 60 % of embryos created in the IVF process) could still prove valuable for stem cell research. However, not all sectors of society are comfortable with

using embryos in research, and some are against any manipulation of an embryo whatsoever. These ethical positions, and several others, are outlined below.

Another source of embryonic stem cells is through a technique called somatic cell nuclear transfer (SCNT), or therapeutic cloning. In contrast to the popular conception of cloning (called reproductive cloning), SCNT does not result in the birth of a complete copy of a human being. It is a technique for creating pluripotent stem cells that are genetically matched to an individual. SCNT begins with an oocyte in which the cell nucleus (and hence all of the nuclear DNA) has been removed to render the egg as genetically “neutral” as possible. The egg is then fused with a somatic cell (usually a skin cell) of a specific individual. The nucleus of the somatic cell then provides the nuclear DNA of the cell, and when activated to divide, each new cell will be a near-perfect genetic match to the donor of the somatic cell. Within a few days, an inner cell mass will appear that contains up to 200 undifferentiated, pluripotent stem cells that carry the genetic imprint of the somatic cell donor. Technically, this dividing cell is referred to as an embryo, and if transferred into a woman’s uterus, it is theoretically possible that it could result in the birth of a child who would be a genetic twin (a reproductive clone) of the somatic cell donor. However, in SCNT, the embryo is never transferred, and harvesting the stem cells at the blastocyst stage ends any possibility that a baby could result. The stem cells can then be cultured and driven to differentiate into a particular cell type to be used as a transplant or to be studied for its disease characteristics.

Religious and Ethical Positions. There is a range of religious and ethical positions regarding the status of the lab-created embryo, or blastocyst, and whether it is acceptable to use it in biomedical research. The most restrictive view, held by Catholics and by some Christian evangelicals and fundamentalists, is that the blastocyst should be accorded the same rights as any fully formed human being. This means that any research that would destroy an embryo is unacceptable to those who hold such an

absolutist view. The Catholic Church, in particular, also opposes the creation of embryos for reproductive purposes because it sees assisted reproduction as a violation of the sanctity of the marriage relationship and its role in reproduction. Other views, however, are considerably more nuanced, and balance respect for the embryo with the need to cure disease and ameliorate suffering.

Critical to all other religious views is the concept of ensoulment – when the developing embryo or fetus acquires a soul. Prior to the nineteenth century, the Catholic Church held to the Augustinian belief that the soul emerges at 40 days’ gestation for males and 80 days’ gestation for females. It was only in 1869 that the Church began to take the view that human life begins at fertilization. It is the concept of ensoulment that either directly or indirectly determines whether embryonic stem cell research is acceptable under certain circumstances. Among mainstream Christian Protestants, the research is generally supported. The Presbyterian Church, the United Methodist Church, the United Church of Christ, the Episcopal Church, and the Unitarian Universalist Association all endorse the research as being in keeping with Christian compassion for the sick and suffering.

The United Synagogue of Conservative Judaism and most Jewish denominations believe that the soul of a human being emerges gradually, and they support embryonic stem cell research. The Muslim religion holds that the soul enters a fetus at 120 days after conception, and most Muslims support embryonic research without reservation. The Hindu religion regards the beginning of life as the moment of conception, but the destruction of an embryo must be weighed against the possibility of doing good. If the embryo can be used to relieve suffering, then its destruction is not prohibited. Although Buddhist scriptures say that life begins at conception, Buddhist countries have some of the most supportive policies toward stem cell research. Buddhist ethics are not intended as laws, but as guidelines to which human beings must bring their own rational interpretations to when deciding what are best for the greatest number of people.

It should be noted that some of the objections to doing research with embryos may be based on misunderstandings of the nature of the blastocyst. One frequently cited objection is that the blastocyst is genetically unique, and this establishes its worth as a human being. In reality, a blastocyst exists prior to the stage wherein the embryo could split to form twins, triplets, or other multiples. Another common objection is that the embryo has the potential to grow into a complete human being, but this argument runs into trouble when one considers that each and every cell of the human body, if cloned, has the theoretical potential to grow into a human being. Many people take the pragmatic view that many thousands of blastocysts now exist for which the most likely fate is disposal as medical waste, and hold that the use of these embryos in biomedical research is a more acceptable choice than their destruction.

Description

Incarnation is one of the central doctrines of Christianity: Along with the doctrine of the Trinity, it was established in the first ecumenical councils. To be a member of the World Council of Churches, and thereby be considered as a Christian church or a denomination, a church needs to confess to both Trinity and the dual nature of Christ, that is, the incarnation.

The Doctrine of Incarnation

According to the council of Chalcedon (451), that solidified the incarnation dogma, “one and the same Christ, Son, Lord, only-begotten, [is] acknowledged in two natures which undergo no confusion, no change, no division, no separation; . . . the property of both natures is preserved and comes together into a single person and single subsistent being (hypostasis); he is not parted or divided into two persons, but is one and the same only-begotten Son, God, Word, Lord Jesus Christ.”

What incarnation means in its classical formulation, then, is that Jesus Christ can be said to be (in some concrete way, not just figuratively) both God and man at the same time. To be more precise, the incarnation requires that the second person of the Trinity (God the Son) became a human being, retained all the attributes necessary for divinity and gained all attributes necessary for being human. Thus, it would be true to say that God the Son has the attributes of Jesus of Nazareth, a Jewish man who lived in first-century Palestine. Further, the Chalcedonian orthodoxy involves that in Christ there is only one subject, not two, and both divine and human attributes are had by this subject. The traditional formula is usually summarized in the claim that Jesus Christ is both God and man, one single person with fully divine and human natures.

The traditional formulation does not explicate how exactly it is the case that one person, one entity, has both divine and human nature and thus both divine and human properties. Instead, the formulation is designed to rule out several other options regarding the relationship of God and Christ. First of all, it rules out a view according

to which Christ was not really human at all, just a God in a human disguise. Conversely, the view that Christ was simply a man with an extraordinary relationship with God is also ruled out by the Chalcedonian formula.

Another view ruled out by the Chalcedonian orthodoxy is Nestorianism (after Nestorius) who claimed that there are two distinct subjects or persons in Christ, one divine and another human. Thus, the divine Christ does not have the same properties than the human Christ. Nestorius' views were condemned by the Church because it insisted that Christ's human properties, such as being born of Mary, must be attributed to the whole person of Christ, not just to Christ's human nature. Otherwise, Mary would only be, as Nestorius had suggested, the Mother of Christ (Christotokos), not the Mother of God (Theotokos). Since the church maintained that Mary did indeed give birth to God the Son, not just a human person, the human properties of Jesus of Nasareth must be attributable to God the Son as well.

The Chalcedonian formulation also rules out what is normally called monophysitism. According to this view, there is only one person in Christ, God the Son, and only one nature, the divine nature. Fearing that this view would evaporate Christ's humanness and the genuine union between human and divine natures, the orthodoxy rejected monophysitism and insisted that there are indeed two distinct natures without confusion. Finally, the Chalcedonian orthodoxy rejected a view known as monothelitism, according to which, there is only one will (or center of agency) in Christ, namely, the divine will. Against this view, it was affirmed that there are in fact two wills in Christ, the divine will and the human will, but the human will is subservient to the divine will.

Problems

As we can see even from this brief overview, the doctrine of incarnation presents quite tricky metaphysical challenges to its adherents (for criticisms, see Hick 2005). Several questions arise. What are persons? What does it mean to have a nature? How can one person have both divine properties and human properties, since it seems

that at least some of them are logically contradictory? In what follows, I focus on the last question and how it has been dealt in contemporary philosophical discussions on incarnation (for overviews of all the following theories, see Marmodoro and Hill 2011).

The last question is known as the incoherence problem. In short, the problem is that it seems logically contradictory for one person to have divine properties and human properties at the same time. The traditional formulation of the incarnation seems to require that Christ is both, say, omniscient and omnipotent as well as to some extent ignorant and lacking certain powers at the same time. One could argue that properties such as being located in space and time (temporal and physical), being physically bounded and having constraints to one's knowledge and power are essential for what makes something a human being. But such properties are in contradiction with properties that, at least for the classical theist, constitute the essential properties for being God. Traditionally, classical theism has understood God being omniscient, omnipotent, perfectly good and loving, timeless, immutable, and simple. Further, these properties are viewed as essential for divinity (that is, what it is to be God) and are held as perfections that a perfect being (God) possesses necessarily. Therefore, if a being that had these properties lost one, say, omniscience, that being would no longer be, or never could have been, the most perfect being and therefore not God.

There is also another problem here, usually called "the biblical Jesus" problem. The problem is that Jesus, as he is portrayed in the Gospels, seems to lack attributes that are essential to divinity in the aforementioned sense. Sometimes, Jesus seems to be ignorant and powerless. One might object at this point and claim that Jesus only seems ignorant and powerless; in reality, he is truly omniscient and omnipotent. This objection could be addressed in many different ways, but the fact is that even if it is correct, no one in her right mind would deny that Jesus is clearly a temporal, changing, and physically bounded being. The problem is that at least these human properties are such that God cannot possess (in the classical view) and still be God. So, even if it

is the case that being human is compatible with having perfect knowledge and perfect power, being God does not seem to be compatible with being physically bounded and changing. In sum, the coherence problem has to do with the seeming incompatibility of certain properties that seem to be essential for being human and properties that are essential for being divine.

Compositional Theories

The classical solution to the incoherence problem is based on the idea that divine and human properties are attributed to different parts of the whole person of Christ. Such proposals might, therefore, be called compositional accounts of incarnation. In this view, the two natures, divine and human, are seen as proper parts of the person of Christ. Divine properties are instantiated by the divine nature and human properties by the human nature. But since these natures compose one single person, we can truthfully say that Jesus Christ as a single person has both divine and human properties. Such a view was typical for Thomas Aquinas and has been subsequently refined and defended in contemporary debates by, for example, Eleonore Stump. According to Stump, the compositional account of incarnation assumes that a whole can be said to have any given property in virtue of the fact that its proper part has this property. Thus, there can be one whole being, God the Son, who has both divine and human properties ascribed to its two distinct parts, the divine nature and human nature. Both divine and human properties are properly attributed to the whole, but this is in virtue of two distinct natures which are the carriers of both divine and human properties, respectively.

The problem with Stump's view is that it is extremely difficult to conceive of how the divine nature could be a concrete part of anything. Divine nature is supposed to be such that it is shared by all the persons of the Trinity. As such, divine nature looks more like a property, an abstract object, rather than something that can be a part of a whole. Brian Leftow's version of the incarnation attempts to circumvent these worries. According to Leftow, Christ is a whole comprised of not human and divine natures, but

God the Son, human body, and a human soul. Here, the divine nature is not a part of anything. Instead, the part is the divine person, God the Son. The problem in Leftow's proposal is, however, that it is now difficult to see, how God the Son would be the subject of Christ's human properties. In this sense, Leftow's view is very close to Nestorianism. In this view, it is not the case that God the Son is identical with Christ, but rather only a part of Christ along with the human parts of Jesus of Nazareth.

Kenotic Theories

Due to the difficulties in the compositional accounts, several contemporary philosophers have resurrected a somewhat minor tradition in Christology usually called Kenotic Christology. Kenosis (gr. *Kenosis* -"emptying") theorists claim that God the Son temporarily "emptied" himself of his divine attributes when existing in his earthly, incarnated state (for overviews, see Evans 2006). This is supposed to solve both the incoherence problem and the "the biblical Jesus" problem. During his earthly life, the Kenosis theorists think that God the Son willfully and temporarily gave up his omniscience, omnipotence, and other divine attributes. This, it is claimed, is the only way to make sense of how Jesus is portrayed in the New Testament: benevolent and knowledgeable, yes, but not infallible or perfectly powerful.

Kenotic theory is not without its problems. It forces its adherents to either reformulate classical divine attributes or give up the idea that these attributes are essential and necessary for divinity. According to the reformulation view, we should understand any given divine attribute to include a "kenotic clause." In the case of omniscience, for instance, such a clause would be something like this: "a perfect being is omniscient unless it freely chooses to be not-omniscient for a certain period of time." However, divine attributes tweaked in this way are in contradiction with the way in which divine attributes are normally understood in classical theism, that is, that they are modally as strong as possible. Thus, the classical theist would say that it is essential for being God that God is necessarily omnipotent *simpliciter*.

Thus, the critic of the kenotic view would here say that the kenotic tweaking of divine attributes is not only in contradiction with classical theism, but also extremely *ad hoc*.

Two-Minds Theories

One of the most widely discussed theory of the incarnation is the two-minds view developed by Thomas Morris (1986). Morris begins by drawing an important distinction between kind natures and individual natures. Having a kind nature means that an individual has the essential properties of some kind or a class of beings. An individual has a human kind nature when the individual possesses all the properties essential for being human. It is possible that an individual has various kind natures and having one is not essential to identity of the individual. Contrary to this, individual natures are necessary: individual natures are clusters of essential properties that make individuals what they are; they cannot lose any of these properties without ceasing to exist. Given this distinction, Morris can now say that even if individual humans (in virtue of having their individual natures) have limited knowledge and power, for instance, it does not follow that having such properties are necessary for being human (having a human kind nature). In other words, being non-omniscient and non-omnipotent are not necessary for having a human kind nature. Morris can thus formulate his often cited distinction between being merely human and being fully human. We human beings are both fully human and merely human: we are fallible, sinful, lack ultimate power; we exemplify human nature only. Given the aforementioned distinctions, this does not prevent an individual from exemplifying also a divine nature, that is, being fully human (and fully divine), but not merely human. Morris' solution is, ultimately, that there is no logical contradiction for an individual being both fully human and fully divine. This, however, works only with respect to attributes like omnipotence, omniscience or perfect goodness: it seems that even Morris has to leave eternity, immutability, and aseity out of the picture.

If this is the case, then what should we say about the New Testament stories that attribute fallibility and other non-divine attributes to Jesus

himself. To solve "the biblical Jesus" problem, Morris claims that Christ had, as it were, two minds or centers of consciousness and agency, one human and one divine. To be fully human, God to Son had to take on both a human body and a human mind. But this does not eliminate his divine powers and knowledge still preserved in his divine mind. Morris, therefore, argues that, in addition to having two natures, divine and human, Christ also has two distinct minds: the divine mind with its divine powers and the human mind. The human mind of Christ would develop as any other human mind having access to the information present in the first century Palestine context. The relationship between these two minds is asymmetrical: the divine mind has full access to the human mind but not vice versa. The idea is that, most of the time, Christ chose to live his life in virtue of his human mind only, blocking his human mind's access to his divine mind. But sometimes, the human mind would have access to the divine mind and its complete knowledge and power.

Although Morris' proposal has been quite popular, there is a problem as well. It seems that Morris' view leads to the thought that there are two distinct persons in Christ: one divine and one human. Normally, we distinguish persons by way of their minds: two minds equal two persons. Morris, of course, claims that such is not the case with Christ: in Christ there is only one person who has two minds. But if we consider belief ascriptions, the issue becomes quite complicated. If Morris is correct, then the person Christ would have some false beliefs in virtue of his human mind (e.g., that the Earth is flat) and true beliefs in virtue of his divine mind (e.g., that the Earth is a sphere) at the same time. The problem is that beliefs are not ordinarily ascribed to consciousnesses at all, but rather to persons. Further, since God the Son is necessarily omniscient, the divine mind of the divine person cannot have false beliefs. Thus, it seems that there must be another mental subject, another person, that is the subject of Christ's false beliefs. Several attempts to develop and refine the two-minds view of incarnation have subsequently been made by, for example, Richard Swinburne, but they are too detailed to be discussed here.

It seems that current solutions to the coherence problem suggest a move away from classic theistic attributes such as immutability and timelessness toward a more temporal and mutable God. Such a move will, of course, be happily endorsed by those otherwise inclined toward open theism or personalistic theism that are critical of the classical attributes of immutability, eternity, and aseity for other reasons as well. However, many defenders of non-kenotic incarnation, such as Morris, insist that there is no reason to give up necessary omnipotence, omniscience, perfect goodness, and other central divine attributes.

Incarnation in the Context of Evolution

Many contemporary theologians seek to understand Christology in the context of biology and physics as well as relating it to contemporary ethical issues. Several Catholic (e.g., Pierre Teilhard de Chardin, Karl Rahner) and Protestant (e.g., Thomas Torrance, F. LeRon Shults) theologians have argued that the classical doctrine of incarnation and its problems are driven by outdated metaphysical categories of “nature,” “soul,” and “person.” This has created a movement among theologians to reformulate the doctrine of incarnation in a way that is supposedly more compatible with contemporary evolutionary view of the world. A Darwinian understanding of these concepts would emphasize the fluidity of these categories: there are no fixed human (or divine) “natures” or “essences” anymore than there are essential differences between humans and animals. These differences are a matter of degree, not strict separation. Further, many theologians argue that metaphysical views of the incarnation are plagued by substance dualism and thus are based on unscientific psychology. Instead, we should adopt a more holistic and multileveled view of human nature and cognition, informed by contemporary cognitive and neurosciences. Persons, in their view, are fully embodied, complex wholes and metaphysical concepts, such as soul or nature, are not adequate to describe this. A radically different ontology is needed, an ontology of relationality and multiple levels, not of fixed essences. In this sense, the incarnation supports a positive and anti-dualistic

view of the created world: by assuming and perfecting material, embodied humanity, God signified that materiality and the material aspects of humanity are valuable and not to be rejected as a necessary evil. They conclude that the notion of incarnation has to be reformulated in order to jettison its metaphysical baggage (For such criticisms, see Shults 2008).

Contemporary evolutionary or dynamic accounts of incarnation tend toward either Kenotic views of the incarnation or jettison the idea of Christ’s essential divinity altogether seeing Him as perfect exemplar of humanity and openness to God. Most contemporary evolutionary Christologies (and theories of the incarnation) are inspired by both Teilhard de Chardin and process theology. These theories usually take Christ to be divine only to the extent that he is obedient to God’s will. By being completely obedient to God’s will and accepting His gift of grace, Christ becomes the perfect man. In this sense, incarnation means simply that Christ is both a new kind of perfected human being and a promise of a brighter future for humans through their God-controlled evolution (For overviews and criticisms, see Deane-Drummond 2009).

One problem with these proposals is that the classical motivation for the doctrine of incarnation is not realized. The early church held that the redemption and salvation of humans is only possible if humanity and divinity are unified in Christ. That is to say, if Christ is not fully human and fully divine, then there cannot be redemption for humanity. If, as many evolutionary or dynamic theories suggest, Christ is a human being who gradually becomes the greatest exemplar of a perfect relationship to the divine, indeed perhaps, a new step in humanity’s evolution, then Christ’s soteriological role vanishes. God the Son does not become incarnated “because of our salvation,” but rather because the emergence of a man with a perfect relationship to God in the course of human evolution is an inevitable step. That is to say, the incarnation (understood in this way) is built into evolution itself, thus being part of the doctrine of creation rather than redemption and salvation.

Further, evolutionary Christologies also seem to make incarnation a highly contingent

event: any human anywhere could have achieved the perfect relationship with God; there was nothing special about Jesus of Nazareth. This, in turn, detaches the doctrine of incarnation from the history of Jesus of Nazareth – from the very history which the doctrine was supposed to explain in the first place. Finally, evolutionary Christologies tend to smuggle strong metaphysical assumptions into their way of understanding evolution, namely, the idea that there is inevitable progress in biological evolution. Most famously, it was Teilhard de Chardin who thought that evolution by natural selection leads inevitably to more and more complex life-forms and toward the increase of charity and goodness. This tendency is also present in theories of incarnation that have their roots in process theology. The problem is that contemporary Neo-Darwinian synthesis is strongly opposed to the idea that there is a necessary and universal development toward complexity, altruism, or the realization of some value. The view is rather that natural selection might lead to increased complexity and altruism, but it is by no means necessary or universal.

Inference of Analogy

Karsten R. Stueber
Department of Philosophy, College of the
Holy Cross, Worcester, MA, USA

The inference of analogy is the traditional manner of conceiving of the method according to which we gain knowledge of other minds. It has been explicitly suggested first by John Stuart Mill (1806–1876). It is based on the assumption that we do not have direct perceptual access to the mental states of other persons. We directly perceive only their bodily movements. Because we assume that similar effects have similar inner causes, we analogically infer another person’s mental states based on our knowledge of how we feel and think when we behave in that manner.

Description

Information security is a field focused on protection of data and the computer systems that work with the data. Security is a combination of privacy, assurance, availability, and integrity. In the last century, information security was focused on availability and assurance only and were the only entities that demonstrated any interest in privacy or integrity. Even so, these concepts were largely academic in nature and provided opportunity for researchers to examine previously undiscovered methods of maintaining privacy and integrity. Private businesses focused their attention on revenue-generating services. Consequently, security to business meant that the business had assurance that computer systems functioned as designed and that the systems were available at all times. Because governments were funding the majority of research in information security, the focus of academia aligned largely with government priorities.

In this century, people are using computer systems for increasing amounts of commerce. Governments have recognized that commerce through computer systems is highly lucrative for businesses and that continuity of business is critical to national and international interests. In this climate, citizens have come under direct attack by those wishing to use computer systems to steal, pressure, slander, and disrupt. Thus, governments have acknowledged information security as a global priority and have created weapons

to attack computer systems and defend against such attacks. For their part, businesses have largely stayed focused on what maintains revenue. Aware of this priority, governments have forced compliance with well-developed information security standards that have emerged from academia and private research groups. Further, special interest groups, such as payment processors and banks, have mandated compliance with their own standards. Academia continues to align with government funding but that funding has broadened in scope to include computer security in increasingly diverse areas.

Self-identification

Science

Computer Science is a field of study that focuses on data as well as the tools that process, store, retrieve, and transport that data. Because computers are so centric to protecting data, Information Security is frequently considered to be a subdiscipline of computer science. However, Information Security has strong ties to law, criminal justice, psychology, business, ethics, and governance. In many academic institutions, degrees in Information Security require specialized courses in topics that go well beyond the typical computer science course requirements. Thus, Information Security is a discipline that stands on its own in many respects but is largely inserted as a subdiscipline of computer science.

Religion

Although security professionals would not self-identify the field of security as a religion, computer security and religion have many parallels. The dominant parallel is the common foundation of “accountability.” Religion describes a God who judges sin, a concept defined as *noncompliance with the will of God*. Security provides oversight to a business or organization by defining, in particular, acceptable behaviors. Non-acceptable behaviors can be considered as sin or *noncompliance with the acceptable use (will of the computer system owners) of a computer system or intended use of the*

underlying data. This parallel of religion and computer security is such that users of computer systems often speak of being “watched” and express guilt when their behaviors fail to meet the standard. This idea of good versus evil is so pervasive that actors and activities in security are generally classified as good or evil and represented as such. For example, good hackers are called “white hats” and the evil hackers are generally called “black hats.”

Characteristics

The information security discipline bears three unique characteristics. The first characteristic is *how goals are expressed*. Most disciplines have the ability to state very concrete goals and measure progress toward those goals. Information security has but one goal: Be more secure today than we were yesterday. The challenge is that being secure against today’s attacks and threats is no guarantee of security against tomorrow’s attacks and threats. Therefore, measuring progress toward security looks more like a two-car race than a “percentage complete” chart. The second characteristic is *the impact to human lives*. A failure to maintain security may mean that people die, get imprisoned, lose wealth, lose jobs, or otherwise suffer. The third characteristic is *the breadth of impact*. Information is a common commodity that now stretches deep into every discipline and aspect of life. The protection of information must be uniquely examined in each space to fit information security into each topic, discipline, and business.

Relevance to Science and Religion

The vast majority of work pertaining to advancing information security is performed within the domain of science. The issues of study are *how to express the security rules* and *how to enforce the rules*. Expressing the rules correctly is critically important in order to properly articulate expectations to computer users, ecommerce buyers, software users, and others in ways that are both clear

and legally binding. These rules are often expressed in company policies, government laws and regulations, industry standards, and contracts. The enforcement of these rules requires many tools from many disciplines including: civil lawsuits, contractually binding consequences, incarceration, personal liability, and computer technologies. Computer technologies are the best and most effective because they prevent breaches in security by strictly enforcing the rules. It also frequently saves the expense and trouble of lawsuits, personal defense, and prison.

Sources of Authority

It is not possible to pick a single person, publication, organization, or institution as “the” authority for information Security. Current trends suggest that the authorities will continue to align around the themes and interests of academia, government, and business. Security does have common ground among the three groups, but the unique interests of each are likely to keep them separate with only limited interactions through journals, proceedings, conferences, and archival publications where experts meet to discuss and cross-validate new developments.

Ethical Principles

The guiding principles in information security are best defined as privacy, assurance, availability, and integrity of information. A violation of any one of these would be an egregious breach of ethics (e.g., a ► [firewall](#) that is not secure by allowing access of private personal information to unintended parties).

Key Values

The key value is “protection.” Security protects institutions and private citizens by blocking harmful and dangerous access or intervention in their computer systems. This protection

essentially limits activity to only activities that are intended and authorized. It further prescribes the specific methods for accessing or changing information. By protecting “what” a user can access with “how” the user access it, the data and the computer systems are often protected. This protection is there for the protection of customers, computer owners, and data owners from both the hacker who willfully is out to damage systems or access private data and also for the “untrained” user who may do “damage” by accident and not intention.

Conceptualization

Nature/World

The natural world for information security is defined as the digital representation of data and derived information in computer systems and devices.

Human Being

Human beings are simply the natural, human computer users, or data about them contained in computer systems.

Life and Death

Life and death are defined in terms of “allowing” or “denying” an activity or in terms of the creation or deletion of data. It is not uncommon for security professionals to describe stopping a user activity as “*killing* the activity” or deleting data as “destroying the data.”

Reality

Reality extends into a virtual, digital world where data is created, stored, transported, transformed, and output electronically.

Knowledge

Knowledge is the imperishable storage of data on the Internet.

Truth

Truth is what actually happened in the real world, as compared to what is recorded in the computer system.

Perception

Perception is a sampling of reality at any instance.

Time

Time is a concept with both a relative and absolute meaning. In relative terms, time is the number of computer cycles allotted to process or transport data. In absolute terms, it translates into the equivalent to the “wall-clock” or “real-world” time.

Consciousness

Consciousness is the awareness of computer-related activities, or perceived security threats.

Rationality/Reason

Reason is the expected behavior of computers as specified by programs running on them. Irrational events occur when computer activity provides unexpected results with respect to the intention of the programmer who created it, usually due to the intervention of “hackers” or unauthorized malicious users.

Mystery

Mystery in information security is simply *what is not discovered* or not *yet* discovered. Often in information security, mystery surrounds the so-called hackers (black hats) who search to damage and steal for personal, corporate, or political gain as well as the so-called good hackers (white hats) who are searching for unauthorized intrusion and unexpected action on computer systems.

Relevant Themes

Security is almost always embodied into rules, similar in nature to those found in religion. Security researchers and professionals assume that these rules must be followed and that everyone/everything else is actively searching out ways to break the rules (or sin). This dichotomy breeds an “us versus them” culture where “they” are assumed to be sinners of the worst sort.

Information-Processing Models (Philosophy of Mind)

Gregory Peterson

Department of Philosophy and Religion, South Dakota State University, Brookings, SD, USA

Deeply informing much of contemporary philosophy of mind is an information processing model of cognition. The initial basis for this model was the concept of a Turing machine developed by Alan Turing and refined by others including John von Neumann, and which underlies the basic architectural concept of modern digital computers. Modern digital computers employ a central processor and separate banks of memory, as well as clearly distinguishing between hardware, the physical components of the computer, and the software, instructions or set of algorithms that dictate the behavior of the computer. The operational structure of digital computers can be understood to parallel or mimic the operations of the human mind. Both operate serially; in the case of the computer, one instruction is processed after another, in conscious reflection, one thought follows another. Both employ memory, and both employ the rules of logic, notably the Boolean operators AND, OR, and NOT. Despite these apparent parallels, growing knowledge of the

details of the anatomy and the operation of the brain has made the comparison tenuous, for although the activity of neurons in the brain may be understood to act somewhat similarly to the logic gates in a computer chip, there is no parallel in the brain to the digital computer's central processor.

As a result, inspiration has been drawn from connectionist models of information processing. Connectionist models often emphasize parallel distributed processing (PDP). Whereas traditional digital computers employ a central processor which acts on each step of an instruction sequentially and through which all instructions must pass, a PDP system initially breaks down a task into a number of smaller tasks and then operates on them simultaneously. Neural network models are a form of PDP that are claimed to closely mimic the operations of neurons in the brain. A feature of some PDP models is that they display emergent behavior, showing higher levels of order that are not apparent at the lower level of processing.

Innate Releasing Mechanism, IRM

Jörg-Peter Ewert

Faculty of Natural Sciences, University of Kassel, Schauenburg, Germany

The term “innate releasing mechanism” belongs to a classical concept of ethology. It refers to a neural sensorimotor interface that mediates between a *key stimulus* and the adequate action pattern. An IRM thus has stimulus recognition and localization properties at its input side and behavior-releasing properties at its output side. The IRM should allow an animal to recognize and respond a behaviorally relevant object that the animal had never encountered before.

The term “innate,” however, is controversial since it may have different meanings, such as present at birth, a behavioral difference caused

by a genetic difference, adapted over the course of evolution, unchanging throughout development, shared by all members of a species, present before the behavior serves any function, not learned.

For example, common toads *Bufo bufo* recognize prey objects by figurative visual features as tests of the prey-catching activity in response to changes in the configuration of dummies have shown: a stripe oriented parallel to its direction of movement (“worm” configuration) is preferred to the same stripe oriented perpendicular to its direction of movement (“anti-worm” configuration). This discrimination is *innate* in the meaning of an ability being present after metamorphosis (from the tadpole stage) and shared by all members of the species. The tadpoles of common toads do not hunt for prey animals; rather they feed on a vegetarian diet.

A neuroethological concept of (I)RM suggests a *command-release system* in which *sensorimotor codes* are involved that can be influenced by motivation and learning. A coded command involves different types of neurons (command elements), each type detecting a certain aspect of a behaviorally relevant stimulus (features, location, etc.). In a certain combination – sensorimotor code – these command elements cooperatively activate a corresponding motor pattern generating system. For example, it was shown that prey-feature-detecting neurons in common toads send their axonal fibers from the visual center (optic tectum) directly toward the motor system (medulla oblongata). Focal electrical stimulation in the layer of the optic tectum that harbors prey-feature-detecting neurons elicited prey-catching behavior. Recordings of such neurons in freely moving toads demonstrated that certain discharge patterns in response to a prey object preceded and – so to speak – predicted prey capture.

Inspection

Linda Sherrell
Department of Computer Science,
The University of Memphis, Memphis, TN, USA

An inspection is a formal review process usually performed by several members of a software development team and at least one person from the software quality assurance (SQA) group. Note that small companies may not have dedicated SQA personnel.

An inspection can be conducted for any software artifact, such as requirements, design documents, or code. As originally defined, an inspection has five prescribed steps:

1. Overview. One of the individuals responsible for producing the artifact highlights the main points in the document and distributes it to the other participants.
2. Preparation. Each participant reviews the document and compiles two lists: (1) a list of likely faults and (2) a list of items that are unclear. Inspection members may also have at their disposal a list of fault types and their frequency compiled from previous inspections.
3. Inspection meeting. One member of the inspection team called a moderator goes through the document, making sure that every line is covered and discussed. The purpose of the meeting is to find faults. Faults are corrected, by the person who made the error or wrote the offending part of the document, at a later time. Within one day of the meeting, the moderator writes a detailed report about the meeting.
4. Rework. The individual responsible for the document makes sure that all faults have been corrected and any other modifications described in the report have been handled. Note that some items may have been incorrectly marked as faults during the preparation time or during the inspection meeting.
5. Follow-up. All changes to the document must be checked to make sure that no new faults have been introduced. If more than 5 % of the

document has been changed or marked as unclear, then a complete reinspection of the entire document must take place.

Installation Art

Deborah Sokolove
Henry Luce III Center for the Arts and Religion,
Wesley Theological Seminary, Washington,
DC, USA

Artwork consisting of objects arranged so as to create an environment into which the viewer can enter, or imagine entering, somewhat as an actor enters a stage set, or to alter the viewer's perception of space. An art installation may be as simple as a few rocks or sticks placed in a circle on the floor of a gallery, intending to evoke a campfire or a sacred grove, or as complex as Chris Burden's 1986 *Exposing the Foundations of the Museum*, in which the artist removed the concrete floor of the newly created Geffen Contemporary at MOCA in Los Angeles, inviting viewers to walk down rickety steps into what resembled an archeological dig. Installation art is often created or modified for a specific site, incorporating elements of the room or building in which it is housed. Installation artworks vary greatly, using natural and human-made materials for their symbolic and metaphoric, as well as visual and tactile, properties.

Instrumental Reason

Eduardo Maura
Facultad de Filosofía, Universidad Complutense
de Madrid (Spain), Madrid, Spain

In general terms, instrumental reason is a specific form of rationality which focuses on effective means to an end and not, as other forms of

practical rationality do, on improving living conditions, promoting reasonable agreement, or human understanding. It is one of the most used and most relevant terms in Critical Theory, particularly M. Horkheimer and J. Habermas. It has traditionally meant domination, manipulation of nature and social relations. For Horkheimer, the sophisticated process of strategic choice of means to an end is regarded as the most representative corruption of practical reason.

Description

Intelligence and the various methods by which it is assessed have progressively evolved during the past 150 years. A brief overview of the contributions of intelligence theorists and researchers speaks of the influence of these scientists on the current understanding of intelligence and its recent developments. An early intelligence researcher, Binet, believed that intelligence was comprised of comprehension, inventiveness, direction, and criticism. In 1927, Spearman suggested that intelligence could be divided into a general factor, pervading all types of intellectual practice, and specific factors, which involve specific tasks (Spearman 1927). The idea of one unifying factor representing intelligence across all domains remains a dominant, if controversial, force in the field.

In contrast to the generalist view, in 1936, Thurstone identified seven primary mental abilities – (1) number facility, (2) word fluency, (3) visualizing, (4) memory, (5) perceptual speed, (6) induction, and (7) verbal reasoning – which would later be utilized as the foundation for the Primary Mental Abilities Tests (Thurstone 1936). These mental abilities almost always correlate with one another, and when factor analyzed, a higher-order general factor emerged. Thus, Thurstone realized that he had to concede to the existence of a general intelligence factor. Spearman, on the other hand, was also forced to accept the group factors identified by Thurstone (Sternberg et al. 2008). Subsequent researchers extended Thurstone’s theory by adding more factors; Guilford, constructed a cube-like model yielding 120 different mental abilities.

Hierarchical models represent a blend of the generalist and multiple domain theories. In 1971, Vernon, for example, proposed a model of mental ability where general intelligence was at the top, verbal-educational and practical-mechanical abilities were at the second level, and the more

specific mental abilities were located at the lower levels (Vernon 1971). An even more detailed hierarchical model using numerous data sets and factor analysis studies was offered by Carroll.

Cattell and Horn proposed the theory of fluid and crystallized intelligence, which is arguably the theory of intelligence with the most impact on IQ testing (Kaufman 2009). They distinguish crystallized intelligence (what a person knows and has learned) and fluid intelligence (how a person deals with a new and different situation). Horn expanded the theory to include more dimensions, such as visualization, short-term memory, long-term retrieval, and processing speed. In recent years, Carroll's hierarchical theory and the Horn-Cattell Gf-Gc theory have been merged into the Cattell-Horn-Carroll or CHC theory (Flanagan et al. 2007). Until then, these and other factorial theories of intelligence had failed to address the processes involved in intelligence. Jean Piaget's theory was among the later theories that sought to examine these processes (Sternberg 2000).

Piaget conceptualized intelligence as a system of translating thinking into actions. He also believed that though intelligence manifests differently with age, we all follow a single path of intellectual development regardless of the rate of development. Wechsler viewed intelligence in light of its interaction with the environment. He conceived of intelligence as a global entity and defined it as the general capacity of an individual to cope with his/her surrounding environment.

Cognitive-processing conceptions of intelligence have also been proposed. These theories seek to understand (often with the use of computers) how humans mentally represent and process information during various tasks. Some researchers, such as Glaser, Pellegrino, Simon, and Sternberg, have recently focused on reasoning and problem solving in a quest to better understand the nature of intelligence (Sternberg 2000). Intelligence is also studied in relation to the external world and its link to culture. Researcher and scholar Robert Sternberg affirms a strong link between intelligence and culture and

states that intelligence is something that a culture creates (Sternberg 2000).

Another view on intelligence is that it is not just a single unitary construct. In 1999, Gardner proposed a theory of multiple intelligences which includes eight distinct intelligence functions that may interact in their production of intelligent behavior: linguistic, logical-mathematical, spatial, musical, bodily kinesthetic, interpersonal, intrapersonal, and naturalist (Gardner 1999). Sternberg's theory of successful intelligence includes creative abilities as one of three essential components, along with analytical and practical abilities (Sternberg 2000). Although not currently adapted into a major IQ test, this theory is the basis for exciting work in college admissions.

Currently, a consensus on the definition of intelligence has not yet been reached among contemporary theorists.

Characteristics

Intelligence influences our thoughts, actions, and interactions with the external environment. Therefore, every activity in which we engage is, in some way, affected by intelligence. Consider the first 20 things you do throughout your day; they all involve and require some degree of intelligence. Even certain instinctive behaviors such as eating require of us some intelligence. We must have the understanding to reach for an edible, nonpoisonous entity as a means for nourishment – a rock or a bottle labeled as snake poison would not be wise choices for sustenance. Intelligence is required in, almost, every activity that involves some level of thought and the use of our minds.

Relevance to Science and Religion

Intelligence researchers have mainly examined intelligence and related constructs through theory, analysis, and the scientific method and have generally not addressed the area of science and religion.

Sources of Authority

This field is driven by empirical research as well as empirical theory. Sources of authority for this discipline are scientific journals, journal articles, research-focused books, standardized IQ tests, authoritative researchers, theorists, and scientists within the field.

Ethical Principles

The ethical guiding principles of this field pertain to the method by which data are collected, the ways by which results are reported, and those affected by the results. Data should not be obtained by means not approved by an Institutional Review Board to make sure that participants are treated in an ethical manner. Reporting the results of the study must be observed with caution, especially in the case of reporting findings that may be undesirable to a particular population. Therefore, generalizations should be made sparingly (while bearing in mind all the specific qualities of the sample population) and with an understanding of the possible consequences of the information on the targeted population. Intelligence score reports can not only influence how one views oneself but also how a culture views itself, as well as how it effects the perception of other cultures of it. Scores may also be wrongfully interpreted or used as a means to discriminate against or pass policies disfavoring groups or classes of people believed to have lower levels of intelligence, heredity, or socioeconomic status. Before reporting the results of a study, we ought to ask whether reporting cultural disparities is indeed of any value other than hinting at differences.

It is important to remember that methods for assessing intelligence and intelligence measures are rapidly improving and therefore recognize that new measures may yield different outcomes. There is much that we know; however, there is much to be learned. In a field such as intelligence, hasty conclusions are not only unethical but bad science.

Key Values

The key values of this discipline include sound scientific knowledge, empirical research, theory, and upholding proper ethical principles.

Conceptualization

Nature/World

The element of nature versus nurture is under study in intelligence research. The findings tell us that intelligence is at least partly genetically determined. However, even though intelligence is thought of as strongly genetic (as demonstrated by twins studies), it can still be influenced by environmental factors and thus be improved (Pearson 2009). In a meta-analysis of 75 studies, children growing up in orphanages were shown to have substantially lower IQ levels than those reared in foster families, showing that the environment does in fact play a role on intelligence. Though we do know that both hereditary and environmental influences impact intelligence, exactly how much of the variance in intelligence is accounted for by either of these elements is yet to be determined.

Human Being

The study of intelligence has found its home primarily the field of psychology, a field dedicated to better understanding and appreciation of the human mind. Endeavors within this field, such as the investigation of intelligence, contribute to our knowledge of that which distinguishes us from other beings.

Reality

Broadly speaking, the study of intelligence assumes a person has knowledge of what is reality.

Knowledge

Crystallized intelligence (Gc), one type of intelligence, involves what a person knows and has learned. Fluid intelligence (Gf), another type of intelligence, addresses how a person handles a new and different situation. Both Gc and Gf contribute to the broader construct of intelligence.

Truth

The essence of science is to seek truths about the universe. In the field of psychology, intelligence is studied through scientific enquiry. Thus, it uses scientific methodology to seek factual knowledge about the construct of intelligence.

Perception

Some of the tasks on an intelligence test, such as reaction time, require better than average perceptual abilities.

Time

As time progresses, more empirical evidence is accumulated on the study of this construct. We know more about intelligence now than we did even ten years ago. Currently, we have more accurate measures for intelligence than we did a few years ago simply because we have gained more knowledge through scientific research.

Consciousness

Most research on intelligence is focused on conscious performance.

Rationality/Reason

Most intelligence tests and theories strive toward rationality and toward reason.

Mystery

There is still a great deal that we have yet to uncover about intelligence. Much remains a mystery; however, much is known and there is great potential for gaining more knowledge in this field.

Relevant Themes

Scientific inquiry and empirical research are of special relevance since it is with rigorous scientific enquiry that we can come close to accurate facts about how intelligence works, how it is used, how it is acquired, how it may be enhanced, and how it relates to other cognitive processes, among others.

Intelligence, Swarm

Xiaohui Cui
Oak Ridge National Laboratory, Oak Ridge,
TN, USA

Related Terms

[Computer science](#)

Studies on Swarm Intelligence are developed from the discoveries and researches of collective behaviors emerged from the social animals or insect group. More than 50 years ago, biologists have reported that a new kind of intelligence form can emerge from some social insects, fish, birds, and mammals. For example, African termites (*Macrotermes bellicosus*) can build nest that may reach a diameter of 30 m and a height of 6 m with complex internal structure (Grasse 1984). These skyscrapers are built by millions of tiny (1–2-mm long) and completely blind individuals. Apparently, in terms of cognitive or communicational abilities, the complexity of an individual termite is not intelligent enough for designing and generating such complex system. Another example of collective behavior is the food recruitment in ant colony. At the beginning of the 1990s, Jean-Louis Deneubourg and his collaborators (1991) found there is a high probability for a colony of ants to find out the shortest path from multiple paths between the food source site and the nest. Many more examples of the impressive capabilities in other biological systems, such as colonies of bacteria or amoeba, fish schools, bird flocks, and sheep herds, share similar collective properties. However, it is hard to explain the complexity of all the behaviors at the colony scale level if only considering individuals of the colony. For a long time, these kinds of collective behaviors that emerge from social insects or animal society have remained mysterious and appear to happen as if an “invisible hand” or leader inside the colony coordinates the individuals’ activities. The power of the collective behavior of social insects has also inspired novelists. Michel Crichton, in his novel “Prey,” describes a swarm of nanorobots that can generate complex intelligence using their collective mind. Early attempts to explain this collective behavior focused on building the connection between the observed complex behavior in the colony level and the behavior of an individual. It was believed that the complex swarm behavior can only be generated by individuals with complex cognitive capabilities. In the research of the social insect behaviors, the queen of an insect colony used to

be considered as the leader of the colony having the capability of collecting the colony’s global information, supervising the worker, and coordinating the behaviors of the whole colony. However, researches indicate that neither queen nor workers have the neuron capability for collecting colony global information, processing the information, and making decision on controlling the behaviors of the whole colony.

The first serious theoretical explanation of the emerging of collective behaviors in social insects was provided by the French biologist Pierre-Paul Grasse. In 1950, Grasse introduced the concept of stigmergy in conjunction with his research on termites. His study has shown that a particular configuration of a termite colony’s environment could trigger a termite to modify its environment, for example, dropping mud in a particular place to build or maintain the nest. The modification in turn stimulates the original or other termites in the colony to further transform their environment. Grasse made a general definition of stigmergy as: “the stimulation of the workers by the very performances they have achieved.” The concept of stigmergy provides a theory for explaining how distributed, ad hoc contributions from individuals could lead to the emergence of large collaborative enterprises.

In recent years, some computer scientists adopt the stigmergy model to solve complex problems and categorized it as Swarm Intelligence. Swarm Intelligence is an artificial intelligence technique involving studies of collective behaviors in decentralized systems. Beni and Wang (1991) first introduced the term of Swarm Intelligence in the context of cellular robotic systems. Bonabeau et al. (1998, 1999) extended the concept of Swarm Intelligence to the work involved with algorithm design or distributed problem-solving devices. He defined the Swarm Intelligence as “any attempt to design algorithms or distributed problem-solving devices inspired by the collective behavior of social insect colonies and other animal societies.” The major concepts underlying Swarm Intelligence include decentralization, stigmergy, self-organization, emergence, and positive and negative feedbacks. Currently, most popular research

directions in Swarm Intelligence are grounded on the following three research areas: Flocking model (Reynolds 1987), Ant Colony Optimization (ACO) (Bonabeau et al. 1999), and Particle Swarm Optimization (PSO) (Eberhart and Kennedy 1995).

The flocking model, first proposed by Craig Reynolds (Reynolds 1987), is a bio-inspired computational model for simulating the animation of a flock of entities called “boids.” It represents group movement as seen in bird flocks and schools of fish in nature. In this model, each boid reacts to the neighboring mates in the flock and the environment it can sense and makes its own decisions on its movement according to a small number of simple steering rules. Three simple steering rules need to be executed at each instance over time. Three basic rules include: (1) Separation: Steering to avoid collision with other boids nearby; (2) Alignment: Steering toward the average heading and match the velocity of the neighbor flock mates; (3) Cohesion: Steering to the average position of the neighbor flock mates. By following these three simple rules, boids in the simulation can quickly form a stable swarm formation, in which every boid has the minimum distance from every other boid and will not move any further than the maximum distance.

The Ant Colony Optimization (ACO) is a heuristic algorithm that is inspired by the food foraging behavior of ants. Marco Dorigo introduced the first ACO system in his Ph.D. thesis (1992). The idea underlying the ACO algorithm is to mimic the ant’s foraging behavior with “simulated ants” moving around a graph searching for the optimal solution. As ants forage, they deposit a trail of slowly evaporating pheromones. All foraging ants use the pheromones as a guide regardless of whether the pheromone was deposited by itself or other ants. Pheromones accumulate when multiple ants travel through the same path. The pheromones on the trail evaporate as well. If an ant reaches the food first and returns to the nest before others, its return trail’s pheromone is stronger than other trails on which

ants have not found food or have longer distances from the food source because the return trail has been traveled twice. This high volume of pheromone volume attracts other ants to follow this trail. The more the trail is traveled, the stronger the pheromone content on this trail will be. The level of pheromone on other less traveled trails will decrease since fewer ants travel those trails and the pheromone evaporates. Eventually, the trail with highest level of pheromone and traveled by most of foraging ants will be the shortest trail between food sources and nest.

Particle Swarm Optimization (PSO) is a population-based stochastic optimization technique that can be used to find an optimal, or near-optimal, solution to a numerical and qualitative problem. Inspired by the social behavior of flocking birds or a school of fish, Eberhart and Kennedy originally developed the PSO in 1995 (Eberhart and Kennedy 1995). In PSO, birds in a flock are symbolically represented as particles. These particles can be considered as simple agents “flying” through a problem space. A problem space in PSO may have as many dimensions as needed to model the problem space. A particle’s location in the multidimensional problem space represents one solution for the problem. When a particle moves to another location, a new solution is generated. This solution is evaluated by a fitness function that provides a quantitative value of the solution’s utility. The velocity and direction of each particle moving along each dimension of the problem space are altered at each generation of movement. It is the particle’s personal experience combined with its neighbors’ experience that influences the movement of each particle through a problem space.

Swarm Intelligence is a growing research field for solving distributed problems. It offers an alternative way to design system that has traditionally required centralized control and extensive preprogramming. However, because the pathways to solutions are not predefined but emergent, there is no general guideline on how to design a swarm intelligent system. The system

designer has to rely on trial and error process to determine how the agents of a swarm-based solution should be programmed. Currently, most of the Swarm Intelligence studies and applications are mimicking the collective behaviors of social insect or animal society. These Swarm Intelligence applications seek to solve tasks strictly relying on simple individual capabilities, local interaction mechanisms, and indirect communication (stigmergy). Adaptation, computational intelligence, cognition, and other sophisticated capability are absent at the individual level in current Swarm Intelligence system.

Description

Since the early twentieth century, conceptions about intelligence in the West have been shaped by the work of Alfred Binet and the “IQ test” that he developed in Paris. In an attempt to devise a metric that could predict student success in school, Binet and those who followed him designed questions that measured verbal memory and reasoning, numerical processing, and the capacity to understand logical sequences. While these tests were useful in predicting outcomes in environments that relied heavily on such processing, such as schools, they sharply restricted what could count as intelligence. Such a one-dimensional definition of intelligence, supported by psychometricians who consistently cited data culled from paper-and-pencil tests, has remained dominant in many Western nations as well as other countries influenced by Western educational and/or testing practices.

Yet debate over this term, and this concept of intelligence, has continued over the ensuing decades. There have been challenges to the narrow limits of what counted as intelligence, debates about the heritability of intelligence, and allegations with respect to the possible biases of intelligence tests. Toward the latter part of the twentieth century, these discussions were heightened because of new discoveries about the

differentiation of the brain and the localized nature of many mental capacities.

It is within this environment that Howard Gardner approached the question of what counted as an intelligence. Working with brain-damaged adult patients and artistically talented children, he noted repeatedly that skills and capacities are not evenly distributed. That is, a person may be very good at learning a foreign language but unable to find her way around a new environment or learn a new song. The opposite profile of capacities can also be encountered. Such recurrent discoveries led him to think of the human mind less as a monolithic machine and more as a set of relatively discrete faculties. Conducting research and synthesizing findings in psychology, neurology, sociology, anthropology, the arts, and humanities, Gardner was led to proposing the existence of seven relatively autonomous intelligences, described in detail in his 1983 work, *Frames of Mind* (Gardner 1983).

In MI theory, an intelligence is defined as “a biopsychological potential to process information that can be activated in a cultural setting to solve problems or create products that are of value to a culture” (Gardner 1999, pp. 33–34). Aside from broadening the definition of intelligence to extend well beyond skills needed to succeed in certain kinds of schools, Gardner also posited that intelligences are capacities and potentials that can be activated to varying degrees, depending on opportunity and motivation.

Gardner drew his criteria for an intelligence from a variety of sources. Two emerged from biological sciences: (1) potential isolation by brain damage and (2) an evolutionary history and evolutionary plausibility. The first drew on his experience as a neuropsychologist of seeing how brain damage can severely affect one set of capacities yet leave another untouched; the latter criterion indicated why an intelligence may have contributed to survival of the species. Two criteria came from developmental psychology: (3) a distinct development history, along with a definable set of expert “end-state” performances and (4) the existence of idiot savants, prodigies,

and other exceptional people. Two criteria were drawn from traditional psychology: (5) support from experimental psychological tasks and (6) support from psychometric findings. The final pair of criteria came from an analysis of the candidate capacity: (7) possessing an identifiable core operation or set of operations (such as command of syntax in the case of linguistic intelligence) and (8) susceptibility to encoding in a symbol system.

Gardner initially proposed the existence of seven intelligences, and information on them is available in many sources. We offer a brief list here:

1. Linguistic intelligence: involves the sensitivity to spoken and written language, the ability to learn languages, and the capacity to use language to accomplish certain goals. Exemplified among lawyers, writers, and speakers
2. Logical-mathematical intelligence: involves the capacity to analyze problems logically, carry out mathematical operations, and investigate issues scientifically. Most apparent among mathematicians and scientists
3. Musical intelligence: involves skill in the performance, composition, and/or appreciation of musical patterns
4. Bodily kinesthetic intelligence: the potential of using one’s whole body or parts of the body to solve problems or fashion products
5. Spatial intelligence: the potential to recognize and manipulate patterns of wide space as well as more circumscribed areas
6. Interpersonal intelligence: the capacity to understand the intentions, motivations, and desires of other people and to work effectively with others
7. Intrapersonal intelligence: the capacity to understand oneself and to use such information effectively in regulating one’s life

More recently, Gardner added an eighth, or “naturalist intelligence” – the capacity to make consequential distinctions in the world of nature, and he has speculated about a ninth or “existential” intelligence – see below for more on this intelligence.

Self-identification

Rather than a discipline, MI is a theory about the nature of intelligence. It has contributed to debates concerning the nature of intellect, as well as the identification of computational capacities that make various disciplines, professions, and crafts possible. Perhaps less predictably, it has considerable impact worldwide among classroom educators who have applied the theory in novel ways. As a social science synthesis, MI theory is subject to verification and revision. However, the theory is less likely to be revised as a result of experiments but more likely to be revised in light of new findings that revise the original synthesis.

Characteristics

MI is distinct from other theories of intelligence in a number of ways. First, most theories of intelligence are monolithic. That is, they measure and account for only one kind of intelligence, typically a combination of linguistic and logical capacities. The theory of multiple intelligences seeks to identify and examine a wide and potentially expanding range of intellectual capacities. While other theories consider the pluralistic nature of intelligence, these theories are typically limited by their exclusive reliance on paper-and-pencil tests. MI, on the other hand, draws its explanatory power from surveying different academic literatures and kinds of empirical data, in an attempt to tease out the range of human capacities and potentials.

Relevance to Science and Religion

In the years following the publication of *Frames of Mind*, Gardner was often asked if more than seven intelligences existed. In *Intelligence Reframed* (Gardner 1999), he considers the existence of a spiritual intelligence. In raising this possibility, he considers three possible meanings

of the spiritual intelligence: (1) a concern with cosmic or existential issues, (2) the achievement of a state of being, and (3) a specific set of beliefs and practices, as found in organized religions.

Inasmuch as engagement with spirituality or religion entails a concern with existential issues, it may qualify as an example of spiritual intelligence. Through myth, art, ritual, and philosophy, religious traditions have taught answers to, or at least ways of thinking about, the origin of life, the meaning of death, and the purpose of existence. Yet, Gardner cautions that identifying the exact content that is mastered in the spiritual realm is more difficult. Many traditions argue that there is specific knowledge to be acquired, but as the history of religions shows, fierce battles over doctrine are rarely resolved definitively.

By the same token, it would be inappropriate a priori to identify beliefs or morals that must be adopted by an individual. It is also worth noting that some analysts characterize the realm of spirituality as more affective and emotional, rather than purely cognitive. While it seems likely that one can identify the ability to train one's mind through meditation or prayer, it is far from evident exactly what content would be mastered within a spiritual intelligence.

Citing the impact that figures such as the Dalai Lama and Mother Theresa have had on others, Gardner also considers the possibility that the potential to influence others may constitute spiritual intelligence. And indeed, when it comes to identifying exemplars of spiritual intelligence, religious communities have long recognized those with advanced understanding or the ability to achieve trance states or be in touch with psychic realms. Yet, this phenomenon becomes problematic in the case of individuals who operate outside of a defined religious system, such as those who gain spiritual nourishment and insight on their own, through activities ranging from hiking to meditation to mathematical problem solving.

In light of this analysis, Gardner, in distinction to others who argue the contrary, has tentatively concluded that a spiritual intelligence does *not* exist, finding it more comfortable to speak of

a potential to engage in thinking about cosmic issues. He writes in *Intelligence Reframed*:

I think it best to put aside the term *spiritual*, with its manifest and problematic connotations, and to speak instead of an intelligence that explores the nature of existence in its multifarious guises. Thus, an explicit concern with spiritual or religious matters would be one variety – often the most important variety – of an existential intelligence. (Gardner 1999, p. 60)

Gardner argues that existential intelligence, which he identifies as the cognitive strand of the spiritual, is the best potential candidate for an intelligence. Its core capacities would include the abilities to reflect on what is not easy to perceive directly since it tends toward the infinite or infinitesimal, to locate oneself and others on a macro- and microcosmic level, and to process existential features (such as life and death) and experiences (such as love, sadness, emotional attachment, and immersion in a work of art) of the human condition.

Existential intelligence exhibits many of the criteria for an intelligence. It is valued in nearly every human culture, and its meanings are encoded in networks of symbols (e.g., the crucifix, the Torah, the Quran, the Ten Commandments, icons of saints and deities). There are clear stages of sophistication and mastery, with exemplars who have reflected at length on cosmic issues. Although biological evidence is less straightforward, Gardner suggests that the evolution of the human brain by the time of the Stone Age enabled human beings to reflect upon and integrate into artistic representation questions about the nature of life and death, conflict and reconciliation, and nature and culture. Indeed, concern with the ultimate seems to distinguish humans from other species.

Although information from the biological sciences is less forthcoming, evidence concerning brain damage and, in particular, temporal-lobe epilepsy is suggestive. Among the symptoms displayed by such individuals is hyperreligiosity, along with a tendency to transform minute experiences into a launchpad for extended introspection. Psychological evidence is less robust since no reliable psychometric test is correlated with

concern with cosmic issues. However, from a phenomenological perspective, reflection on cosmic matters in response to significant pain or peak/mystical states seems to suggest the stimulation of certain brain centers and the release of neural transmitters in such states. Given the still incomplete evidence with respect to existential capacities, Gardner accords this candidate the status of a “half-intelligence” status, pending the accumulation of further evidence, particularly from the biological sciences.

More generally, the theory of multiple intelligences can make useful contributions to discussions on science and religion. The theory can help frame the ways in which religious and spiritual concerns dovetail with the intelligences involved in solving problems or producing works of art and philosophy. In the classroom, educators of both religion and science can and have utilized the theory, using MI-informed entry points to facilitate students’ understanding of curricular material.

Sources of Authority

The theory of multiple intelligences is inherently interdisciplinary, as it draws on scholarly research in psychology, neuroscience, cultural studies, and other social and behavioral sciences.

Ethical Principles

The theory of multiple intelligences is amoral. Like any tool or any scientific finding, an intelligence can be used benignly or for ill. Although some have attempted to argue for the existence of a moral intelligence, Gardner does not believe that morality satisfies the aforementioned eight criteria for the status of an intelligence.

Struck by the paradox of intelligence as amoral, Gardner and colleagues subsequently developed the GoodWork Project, a multiyear, multisite study of how leading professionals engage in work that is excellent in quality, highly ethical, and personally meaningful (Gardner et al. 2001). A primary goal of the project has been to

determine how leading individuals make use of their intelligences: what role models do they choose? How does their personal history impact their choices? How do they conceive of their personal, professional, and global responsibilities? The project assumed that since human intelligence is amoral and subject to either good or ill use, it is important to understand how some individuals deploy their intelligence(s) to produce good for their communities. In the end, each individual must decide how to use his or her intelligence.

Key Values

As a scientific theory, MI is informed and bound by the values common to all scientific research, such as integrity, publication, susceptibility to critique, and revision. As an academic researcher, Gardner is keen on following the ways in which MI is used by educators, many of whom have integrated its insights into pedagogical techniques, such as the use of a variety of entry points in the communication of important theories, findings, concepts, and insights.

For the most part, Gardner has adopted a hands-off approach and allowed educators to adapt MI in whichever ways seem most useful. Nonetheless, he has on occasion spoken out when encountering egregious misapplications of the theory. In particular, he challenged the use of MI in one Australian state's school system. The architects of that curriculum had asserted that various racial and ethnic groups possessed certain intelligences, while lacking others. Such uses of MI clearly misunderstand the purpose and scope of the theory. The precepts of "good work" indicated that this misuse should be labeled as such.

Conceptualization

Nature/World

As a theory focused on explaining human cognition, MI theory does not have a stance on the status of nature or the world. Discussions of this

sort are beyond its purview, although reflection upon it would fall under the category of existential intelligence. Of course, the naturalistic intelligence focuses particularly on distinctions in nature, while other intelligences are focused more on human dimensions.

Human Being

Living, conscious creatures whose psychological makeup consists, in part, of multiple biopsychosocial potentials or capacities that enable them to solve problems or create products that are valuable in at least one society.

Life and Death

As a theory focused on explaining human cognition, MI theory does not have a stance on the origins of life and the nature of death. Discussions of this sort are beyond its purview, although reflection upon it falls under the category of existential intelligence.

Reality

As a scientific theory focused on explaining human cognition, MI theory assumes the existence and explicability of reality. That said, it does not have a further stance on the nature of reality. Discussions of this sort are beyond its purview, although reflection upon it falls under the category of existential intelligence.

Knowledge

Consists of data to be organized and utilized by individuals to solve problems and create products, through the lenses of various intelligences.

Truth

As a theory focused on explaining human cognition, MI theory does not have a stance on the nature of truth. Discussions of this sort are beyond its purview, although reflection upon it falls under the category of existential intelligence.

Perception

MI theory focuses on how individuals process and make sense of data, rather than on the mode

by which data are detected. That is, there are no visual or auditory intelligences per se. Rather, the intelligences operate on information, independent of how that information is transduced via one or more sensory organs.

Time

As a theory focused on explaining human cognition, MI theory does not have a stance on the nature of time. Discussions of this sort are beyond its purview, although reflection upon it falls under the category of existential intelligence.

Consciousness

MI theory focuses on the ways in which human beings process and make sense of information and has not developed a robust conception of consciousness.

Rationality/Reason

MI theory does not explicitly deal with the nature of rationality and reason, but insofar as they constitute the capacity to generate conclusions based on data, rationality/reason may be considered a faculty that enables one to solve problems. When classically defined, rationality/reason may be taken to refer to a capacity to make sense of data specifically through linguistic and/or logical-mathematical intelligence, but they may also be considered as facets of other intelligences.

Mystery

As a theory focused on explaining human cognition, MI theory does not have a stance on the nature of mystery. Discussions of this sort are beyond its purview, although reflection upon it falls under the category of existential intelligence.

Intelligent Design

Jakob Wolf

Department of Systematic Theology, Faculty of Theology, University of Copenhagen, Copenhagen K, Denmark

Description

The idea of intelligent design in nature and the universe has a long tradition. The German philosopher Immanuel Kant (1724–1804) thought that this idea was as old as the reason of man. It can be found both in Western and non-Western religion and philosophy. You can find arguments for intelligent design in nature defended not only in ancient Greek philosophy but also in Hindu, Chinese, Islamic-Persian, and other non-Western traditions.

In Western tradition, Anaxagoras of Clazomenae (500–428 BC) is regarded by many as the first in ancient Greek philosophy to attribute the evident structural harmony and order in nature to some form of intelligent design plan rather than the chance concurrence of atoms. Anaxagoras believed a cosmic “Mind” ordered a primeval chaos of very small particles.

Socrates (470–399 BC) and Plato (427–347 BC) argued that cosmic and material order is the result of “Ideas” and “Mind” and that the order and design of the world can only be sustained by virtue of a Mind. Aristotle (384–322 BC) believed the organic analogy was the best to describe the natural world, which he thought functioned according to ends and design that was built into nature. Because his thoughts were adopted by Christian thinking in the Middle Ages, his ideas for centuries had an enormous influence on the thinking in western Europe.

The Stoics who dominated philosophy for almost 500 years in the ancient world adopted some of Aristotle’s teleological ideas. The Stoic cosmos was indeed an intelligently designed cosmos. The Stoics supported enthusiastically the design argument in all its forms.

In medieval Christian philosophy, arguments for intelligent design in nature are found in the widespread so-called teleological or physicotheological proofs of God's existence. Thomas Aquinas (1225–1274) completes the conversion of Aristotle's philosophy and teleological world view to Christianity. He had five arguments for the existence of God. In his famous *Fifth Way*, he used a teleological design argument to prove the existence of God. He argues that things in nature, which have no intelligence, move as if guided by deliberate ends, like an arrow shot by an archer.

In the Renaissance and in more modern time design, arguments are found in science and philosophy by people like Johannes Kepler (1571–1630), Galileo Galilei (1564–1642), Isaac Newton (1642–1727), Robert Boyle (1627–1691), Gottfried Leibniz (1646–1716), and William Paley (1743–1805), just to mention a few (Barrow and Tipler 1986).

Like design arguments had their critics in ancient Greek philosophy, they have their critics in modern time. David Hume (1711–1776) and Charles Darwin (1809–1882) represent the most effectual critics of the design argument in philosophy and science in modern times. When Kant said that the design argument was as old as the reason of man, you might add that the critique of the design argument is just as old and persistent.

Kant himself represents an interesting middle position in this never-ending discussion. On the one hand, he rejected the physicotheological proof of God's existence, though he said it deserved to be mentioned with honor; on the other hand, he claimed that it is inevitable to presuppose intelligent design in nature. The biological sciences must presuppose design and teleology, but these notions are not part of biology strictly taken as natural science.

The recent developments within the tradition have taken place in ► [astrophysics](#), origin-of-life studies, evolutionary biology, and ► [philosophy of science](#). Since the beginning of the 1990s, arguments for intelligent design in nature have had a renaissance especially among scientists in USA with some affinity to religious communities such as creationism and evangelism.

In the mid-1970s, physicist Brandon Carter drew the attention to the fact that the laws and constants of physics seem to be “fine-tuned” for the universe to be suitable for life. Since then, a number of physicists and astronomers have supported the fine-tuning hypothesis: John Barrow and Frank Tipler, Guillermo Gonzales and Jay Richards, Paul Davies, Stephen Hawking, and others. The fine-tuning hypothesis is a design argument. It is being opposed by the theory of the multiverse, which claims that there are many “universes” with different laws and physical constants, so “our” universe is just a chance occurrence.

In origin-of-life studies, the central question is how molecules that are able to self-reduplicate and contain coded chemistry can evolve. As early as 1968, Michael Polanyi pointed out that the information in code molecules transcends its chemical medium. In the mid-1980s, Walter Bradley, Charles Thaxton, and Roger Olsen suggested that the emergence of “coded chemistry” is best explained by intelligent design. Since then, some scientists have tried to underpin the design theory within origin-of-life studies: David Berlinski, Stephen Meyer, and others. In evolutionary biology, especially biochemist Michael Behe (Behe 1996), but also others, has argued for the relevance of intelligent design theory. In 1996, Behe claims that tiny molecular machines, such as the bacterial flagellum, are “irreducibly complex.” Structurally, they resemble a mousetrap. The system only works if all the parts are in place. Natural selection working on random mutations cannot build such a system, because it can only build systems one small step at a time, by traversing a path in which each step provides a present survival chance for the organism. It cannot select for a future function. Only an intelligent agent can do that. On the macroscopic level, it is a problem to Darwinian theory that in the fossil record the three-dimensional complexity of many diverse animal body plans show up at, geologically speaking, more or less the same time, the so-called Cambrian explosion. Darwinian theory of gradual evolution does not predict the sudden appearance of complexity. Sudden innovation

and increase of information are always due to intelligent agency, intelligent design theorists argue.

The recent attention to intelligent design arguments in science has, in philosophy of science, revived the idea of a correspondence between human rationality and rationality in the universe. The question is: how can it be that man using scientific investigation relatively effectively can discover important aspects of the truth of about nature? Or as Nobel Prize winner physicist Eugene Wigner points out, the enormous applicability of mathematics in natural science is a mystery, there is no rational explanation. Albert Einstein spoke of the laws of nature as “reason incarnate.” The universe is intelligible because it incarnates reason. Philosopher Anthony Flew, a former outspoken atheist, in 2004, puts forward a strong support for the design argument based on Einstein’s reflections and recent developments in astrophysics and microbiology. In continuation of Behe’s concept of “irreducible complexity,” mathematician and philosopher William Dembski elaborates a mathematical model for detecting intelligent design in nature (Dembski 1999).

Self-identification

Science

The intelligent design community in USA does self-identify intelligent design theory as science. Michael Behe argues that the design inference is inductive and therefore scientific. William Dembski argues that not only unintelligent causes like mechanical laws of nature and chance should be allowed in scientific explanations but also an intelligent cause. Others argue in continuation of Kant that the idea of intelligent design in nature is not a scientific but a prescientific concept. Intelligent design is a philosophical idea (Kant 1966).

Religion

It does not self-identify as a religion. It does not exclude religious implications, but it does not require religious premises. Many critics of the intelligent design movement in USA, however,

see it as creationism in disguise. It denies the religious character of the theory in order to have intelligent design theory taught in public schools. In fact, intelligent design proponents are trying to promote Christian ideas (Numbers 2006).

Characteristics

This tradition is distinct by being in its core a philosophical tradition. It is neither science nor religion, but it has the closest connection to science and some relation to religion. It is not science in a modern sense where science is defined by methodological naturalism which excludes intelligent causation. Rather, it can be categorized as what was formerly called natural philosophy. It is not religion because it is based on perceptions of nature and not belief in holy books or religious beliefs. The relationship between intelligent design in nature and religion is that the religious interpretation of intelligent design in nature as an expression of a transcendent creative power is a further interpretation of what or who the designer may be. The religious interpretation is a possible, but not a necessary, interpretation.

Relevance to Science and Religion

The tradition is highly relevant to the scholarly area called ► [science and religion](#). The idea of intelligent design in nature can be used to bridge science and religion. As being a presupposition for science and being open to a religious interpretation, the concept of intelligent design bridges science and religion without confusing science with religion.

Sources of Authority

The sources of authority for this tradition are classical and modern religious, philosophical, and scientific texts such as the writings of Plato, Aristotle, the Stoics, Thomas Aquinas, Kepler, Newton, Kant, Paley, etc. The classicistic

character of the texts and the quality of the science and the philosophical reflections make these sources authoritative.

Ethical Principles

The search and respect for truth.

Key Values

The love for truth and honoring nature. In this tradition, it is argued that nature has an intrinsic value, which provides nature with an ethical quality. It is critical to all theories of the universe and nature that reduce nature to mechanical processes and chance events, which remove all intrinsic value from nature

Conceptualization

The tradition of the idea of intelligent design in nature does not have any special definitions of the mentioned phenomena. It follows the traditional definitions from philosophy and science.

Relevant Themes

The concept of intelligent design in nature is especially relevant as a concept that bridges science and religion. It is critical to the way science and religion is bridged in the concept of theistic evolution. Here, God is seen as a primary cause behind the Darwinian mechanism. God creates the universe and then leaves it to evolve by itself. In this model, the concept of God is reduced to a deistic concept, and nature is reduced to be the result of meaningless mechanisms and chance events.

Intentionality

Bertram F. Malle
Department of Cognitive, Linguistic, and Psychological Sciences, Brown University, Providence, RI, USA

The quality of a behavior being intentional – that is, chosen, purposeful, done for a reason. Research shows that five components have to be present for people to consider a behavior intentional: the actor must have had a desire for an outcome, a belief that

the behavior will lead to the outcome, an intention to perform the behavior, awareness of fulfilling that intention while performing the behavior, and skill to perform the behavior.

Interreligious Studies

Paul Hedges

Department of Theology and Religious Studies,
University of Winchester, Winchester, UK

Description

The term “Interreligious Studies” is a relatively new one within academia, but one that is becoming frequently employed. Its basic meaning refers to studies involving two or more religious traditions or groups; however, it can bear a number of different connotations within this broad area. For instance, it is often seen linked to the term “Intercultural Theology,” a term that usually refers to recent development within ecumenics and mission studies where emphasis moves from mission as conversion toward developing an inculturated theology and dialogue with the religious other. In this context, although stressing the Religious Studies context rather than the theological, it may carry a theological tone where study between religions for mutual enrichment is key. However, this is not its only usage, and it may refer to the study of different religions in meeting, encounter, and activism. Here, a more “secular” than theological concern may be involved based in, for instance, a sociological exploration of the role of different religious traditions in social inclusion, or activism around issues like the environment. Another area that may be of concern in Interreligious Studies, and where, probably, the most common usage of

“interreligious” on its own is found, is as an alternative or synonym to “interfaith” in the phrase Interreligious/Interfaith Dialogue. This preview of three sample areas may suggest a variety of different usages, and this is indeed the case, however, this does not make the term too broad. Across its various usages, Interreligious Studies often tends to imply more than simply a study of two or more religions, but is about studying the dynamic encounter and interaction between them. This may involve hermeneutics, dialogue, historical encounters, or other areas; moreover there is normally an interest in the meaningful growth, enrichment, and benefit gained in this. Much of its focus will be on modern and contemporary issues; however, for particular scholars historical studies may be the focus.

Given its broad usage and general intentions, Interreligious Studies has a certain affinity with a number of other academic growth areas, particularly Intercultural Theology (referred to above), Comparative Theology, Comparative Religion, and studies in such areas as the Theology of Religions, Multiple or Dual Religious Belonging, and Interfaith Dialogue and Relations. It may, therefore, be seen, in some ways, as an interface between a more traditionally secular Religious Studies discipline, and a more traditionally confessional theological discipline. It is certainly a multidisciplinary enterprise employing historical, sociological, anthropological, psychological, philosophical, and other tools; in this regard, it stands clearly in the tradition of Religious Studies, perhaps as a more engaged aspect of Comparative Religion. However, it can be seen as something more, standing neither in Theology per se, nor simply Religious Studies, with some people involved in the research area sitting more comfortably in Sociology or Global Studies. Concerns with the social issues, political concerns, and other factors related to religious interaction make it a transdisciplinary or interdisciplinary subject area. While many involved may come from one particular background, Interreligious Studies involves the recognition that as a subject area it interacts with many disciplines and areas of life and study.

Self-identification

Science

In the broad sense of an area of study, or field of knowledge, Interreligious Studies can be seen as a science like the fields of Religious Studies and Theology. However, in the more restricted sense commonly used today, in reference to the natural and mathematical sciences, it is not a science. Nevertheless, in the mainland European context at least, many of those committed to Interreligious Studies may see their work as “scientific” in that it holds to strict qualitative and/or quantitative methodologies, criteria, and disciplinary guidelines that prescribe it as a genuine academic area of study.

Religion

It is not a religion, however, as outlined in section “[Description](#)”; there may be those who see its study as providing important details about the contemporary activity of their own religion.

Characteristics

As noted above, Interreligious Studies is a new term, and this has implications for its recognition. It could be argued that it is a development from the older, and well-established, field of Comparative Religion. However, whereas this sought to simply provide an objective historical or phenomenological account of similarities or points of meeting between religious traditions (notwithstanding criticisms of its quasi-theological function under such luminaries in the field as Mircea Eliade), Interreligious Studies is more expressly focused on the dynamic encounter and engagement between religious traditions and persons. Moreover, it can be seen as going beyond Theology and Religious Studies as a transdisciplinary area. Certainly the resurgence of religion in recent decades has seen it growing in importance in relation to areas such as politics, economics, and sociology; therefore, it may be suggested that there is room for a new research field that cuts across subject borders.

Relevance to Science and Religion

The issue of “Science and Religion” is one that would not necessarily be of interest within Interreligious Studies; however, at the same time, it could within certain contexts become a key focus for specific studies. For instance, in studying the historical encounter between Christianity and Islam the passing of Greek wisdom as interpreted and developed by Islamic scholars could be a fruitful area for exploration. It could certainly be usefully employed as an exercise in helping contemporary communities engage more closely in dialogue and understanding. In contemporary concerns, practical issues of interreligious activism may involve issues such as climate change, and as such would again involve directly scientific questions and issues.

Sources of Authority

There are no foundational texts for Interreligious Studies. While, as an interdisciplinary area it is, perhaps, best seen as an approach to looking at things and/or a methodological focus rather than something focused in a specific corpus of works. Nevertheless, it is possible to define scholars whose work fits readily into this research area, some of whom may see themselves as scholars of Interreligious Studies, some are even Professors of Interreligious Studies, whereas others would self-identify in different ways. These figures include Gary Bouma, Marcus Braybrooke, Diana L. Eck, Francis Clooney, Reuven Firestone, Paul Knitter, Oddbjørn Leirvik, Perry Schmidt-Leukel, Paul Weller, Hendrik Vroom, and Frans Wijsen.

Ethical Principles

As an academic discipline those involved in Interreligious Studies would follow any relevant ethical guidelines applicable to their own subject discipline, research methodology, etc. If Interreligious Studies has its own distinct ethical principles it would involve a sensitivity to the varied cultural and religious traditions of its

studies, while scholars involved would, normally, be methodologically self-conscious and would, as a principle, exercise a kind of hermeneutical suspicion about privileged starting points.

Key Values

Given the diversity of perspectives encompassed, key values would vary. However, by and large, some guiding principles could be noted: (1) respect for the other (religious, cultural, etc.); (2) valuing and appreciating diversity; (3) an awareness that truth is plural and diversely expressed; and (4) an interest in social change, particularly involving social cohesion and religious tolerance in society; for many this interest could be spoken of in terms of commitment or desire for these things as areas of scholarly study and personal activism may overlap.

Conceptualization

As a varied academic discipline Interreligious Studies would not have a set conceptualization of any of the following; however, some notes on each can be briefly observed.

Nature/World

These may be conceived from within the religious worldview of the traditions studied.

Human Being

Interreligious Studies will attach worth to the human being qua a human being, possibly based on humanistic ethics or on resources within the religious traditions.

Life and Death

Again, perspectives may depend on the religions studied.

Reality

Interreligious Studies may have a concern with Ultimate Reality if viewed from a more theological standpoint, from a more sociological one its concern may be with the perceived phenomenal

world, that is, how religions contribute, or deter, social inclusion rather than with how they relate metaphysically. However, these two perspectives are not incompatible.

Knowledge

As with much else, attitudes here will depend upon the researcher, their field, and methodology. Some researchers may be very much concerned with questions of how knowledge is obtained, that is, in terms of such things as intercultural hermeneutics, others may question the very concept as an objective category at all following, for instance, lines of thought inspired by the French critical theorist Michel Foucault where knowing is an act of power and what is known is shaped and determined by the means of knowing.

Truth

Questions of “truth” may not be of much concern to people involved with the pragmatics of interreligious social action, while the question of getting results may be valued. However, within religious contexts, truth may play a key role; indeed, it is likely to be held that lasting benefits must in some way be aligned with what is “true.”

Perception

Biological questions of what perception involves are unlikely to be of concern. However, in philosophical terms, what shapes what we perceive, the way we perceive it, etc. Then it will be related to some of the lines of thought discussed under “knowledge” and “truth.”

Time

Unless issues about the different perceptions and understandings of time between religious traditions are raised, that is, whether it is conceived in linear or cyclic terms and the effects of this on thought worlds, actions, etc. it would not often be of much concern in most circumstances.

Consciousness

Concepts of this vary vastly between different religious traditions, and social and cultural groupings and so may become a topic of discussion

among those concerned with the more abstract and metaphysical aspects of Interreligious Studies.

Relevant Themes

These would be strategically relevant issues rather than ones intrinsic to Interreligious Studies per se, and might include such things as follows: Areas of common concern in activism, for instance, where religious groups come together to discuss climate change, global warming, stewardship of the planet, etc.

The shared history of scientific endeavor that links Islam and Christianity (and also Judaism) could be a useful area to link these religions in a sense of a shared history, which would also bring it into intimate relation with certain secular realms of thought. For instance, the portrayal of religion as “irrational,” “anti-religion,” and “dangerous” by some of the New Atheists would be shown to be erroneous if the role Islamic scholars played in preserving and improving on the Greek scientific legacy and passing this to Europe, allowing that continent’s own Renaissance and moves to modernity, was more widely known.

Areas of scientific study could be applied in specific instances, for example, studies have been done on the brainwaves of people meditating or praying, showing that this activity alters the patterns. Comparative studies of religious experience or near-death experiences could also be undertaken which would have a possible application within Interreligious Studies.

Acknowledgments My thanks go to Dr. Anna Halafoff, Deakin University, Australia, and Dr. David Cheetham, Birmingham University, UK, for comments on an earlier draft that has helped shaped this entry.

An Overview

The primary meaning of Islam is submission or commitment to the Will of God. At the second level, it refers to a religion, a system of beliefs and practices. At the third level, it refers to a culture and civilization created by Muslims. Islam, the second largest of world religions, has guided millions of people over the last 14 centuries to live full and productive lives and given consolation during misfortune and tragedy. Today Muslims number more than one billion and are scattered all over the world but are concentrated in the area stretching from Morocco to Indonesia and from Central Asia to sub-Saharan Africa. In recent years, Islam has grown significantly in Europe and North America as a result of Muslim immigration and local conversion. Many Westerners have been attracted to Islam and find that it satisfies their spiritual needs. This entry will primarily focus on Islam as a religion during its classical period (Shepard 2009; Esposito 2011).

The word *Islam* has different meanings due to different contexts in which it is used. Its first and most basic meaning is submission or commitment to the Will of Allah. The one who makes such a commitment is called a Muslim (an active participle derived from the Arabic verb *aslama*). Hence, the act of accepting Islam is essentially an inward mental action with personal obligations and outward consequences. At the second level, Islam refers to a religion, a system of beliefs and practices. At the third level, Islam refers to a culture and civilization created by Muslims over a period of time that integrated Arab-Islamic principles with ideas from other civilizations, especially Greece, Iran, and India (Shepard 2009; Hodgson 1974).

Allāh is viewed as the unique God – Creator, Sustainer, Ordainer, and Judge of the universe. The Will of God, to which a Muslim submits or commits oneself to, is known through the Qur'an – the Islamic scripture that was revealed to his messenger Muhammad who is believed to be the last in a series of prophets beginning with Adam. The revelation of the Qur'an is considered to be the literal Word of God and it consummates earlier revelations. The basic belief of Islam is expressed in the *shahada* (confession of faith), a declaration which entails that there is no god but Allāh and Muhammad is his Prophet. From this fundamental belief, there are derived beliefs in (1) angels, (2) the revealed Books (especially, the Torah and Gospels), (3) a series of prophets, and (4) the Last Day or the Day of Judgment when each and every soul will be accountable for her deeds and misdeeds. The righteous will be rewarded with paradise and the wicked will be punished in hell. A confession of faith involves further duties that are to be solemnly observed: (1) five daily prayers (*salat*) at dawn, midday, afternoon, sunset, and evening; (2) a welfare tax (*zakat*, about two and a half percent on the capital or income); (3) fasting (*sawm*) from dawn to dusk during the month of Ramadan; and (4) a pilgrimage to Mecca (*hajj*) at least once in one's lifetime if one is able to do it. These four obligations with the profession of faith are called the Five Pillars of Islam (Rahman 1979; Murata and Chittick 1994).

Unlike Christianity, religious dogma plays a minor role in Islam. In fact, the major division in Islam (between Sunnis and Shi'is) is initially attributed to a dispute over who was entitled to lead the Muslim community after the death of the Prophet. However, Sunnis and Shi'is generally agree on the basic principles outlined above. In contradistinction to other religious communities and their scriptures, the Qur'an and Muslim thinkers have accepted the concept of multiple revelations or religious pluralism in the concept of the People of the Book (*ahl al-kitab*). The Qur'an cites three major preceding scriptures: the Torah of Moses, the Psalms of David, and the Gospels of Jesus. It also indicates that there may have been many other prophets who brought revelations. Politically speaking, within a generation after the Prophet's death, the Arabs established an empire modeled on the imperial domains of the Persians and the Romans. Although Islamic law and symbolism played important roles within these empires, they were accompanied by a combination of local customs and administrative edicts derived from non-Islamic sources. Only in the last century, a new kind of Islamic ideology emerged wherein life in its totality could be lived according to Islam. Theories of a modern Islamic state arose mainly in response to Western colonialism and imperialism. Premodern societies ruled by Muslim rulers generally cannot be called Islamic states in the strictest sense of the word (Rippin 2005; Ruthven 2006).

Origins and Early Development

The life of the Prophet Muhammad (c. 570–632 C.E.) in Mecca, Arabia, was crucial to the unfolding of Islam and its ideal. His career revealed the inexplicability of God's activity in the world. His message was to create a just and decent society in which all members were treated equally and with respect. From the beginning of his mission, Muhammad had imparted a sense of brotherhood, a bond of faith among his followers, which helped develop a feeling of close relationship among them. The conspicuous socio-economic content of early Meccan revelations

along with Islamic religious practices further cemented this bond of faith. Following his emigration (*hijra*) from Mecca to Medina where his message was accepted, he was able to create a community-state of Islam in today's parlance. During the Medinan period, Islam acquired its ethos as a religion that united both the spiritual and temporal aspects of human life. Islam, therefore, seeks to regulate the vertical (an individual's relationship with God) and the horizontal human relationships in a social setting. Because of this objective and its emphasis on "community," which includes political, religious, social, and economic aspects, the history of Islam logically also relegates the "religious" to other aspects of culture. Thus, besides Islamic religious institutions and Islamic law, there evolved other institutions governing society that were heavily influenced with Islamic principles (Rahman 1979; Armstrong 1992).

Following the Prophet's death in 632 C.E., the Medinan state expanded with extraordinary speed and, in the course of less than a century Arab-Muslims, had brought a large part of the known world – from Spain across Central Asia to India – under the rule of the caliphs. These lands were now open to the preaching of Islam and, for various reasons, led most people of the conquered territories to accept it. Islam's attractiveness can be attributed to its pure monotheism, concern for human brotherhood, and social justice. The Rightly Guided Caliphs ruled from Medina from 632 to 661. They were followed by the Umayyad dynasty that ruled from Damascus until 750. They, in turn, were supplanted by the Abbasid dynasty that ruled from the newly established capital of Baghdad. In time, Islam spread further through peaceful activities of the Sufis and merchants. Consequently, it facilitated the development of the Arab-Islamic civilization that flourished during the ninth and tenth centuries with accomplishments in philosophy, science, art, and architecture as well as social organization, making it one of the great civilizations of all time. It displayed remarkable adaptive capacity, absorbing many disparate peoples into a single coherent cultural unit stretching

from Spain to Central Asia and northern India. Subsequent Western accomplishments in philosophy and science have been built on the foundations laid by Muslims (Hodgson 1974).

Doctrinal Sources

The central beliefs and practices of Islam are derived from two sources: the Qur'an and the *sunna* of the Prophet. For Muslims, the Qur'an (lit. recitation) is the exact Word of God, revealed word by word to the Prophet Muhammad through the angel Gabriel over a period of 23 years. Most of it was recorded on various materials and also committed to memory. According to Muslim tradition, it was first collected during the reign of the caliph Abu Bakr soon after the Prophet's death. However, the official collection and arrangement of its chapters in its present form was ordered by the third caliph 'Uthman. The Qur'an is considered the most beautiful literary composition in Arabic. Its beauty, in contrast to the Bible, is not the consequence of faith but the very product of divine origin. This aesthetic judgment was reached through literary analysis; hence, its beauty is held not only by the Muslims but also by the non-Muslims conversant with the literary aesthetics of the Arabic language. Thus, the Qur'an is unique among the religious scriptures of mankind in the sense that the veracity of its scripture rests on the fact of its sublime beauty. This is the real reason for its greatest veneration by the Muslims. Its recitation signifies divine participation in the divine drama. As a literary monument, the Qur'an stands by itself, a unique composition in Arabic literature, having neither forerunners nor successors with its idiom (Gibb 1963; Sells 2002).

Muslim orthodoxy's objection to translation stems mainly from doctrinal consideration that it is the Word of God. Doctrine also holds that it is the miracle of the Prophet. Those who permit translation, on the other hand, argue that the Qur'anic message is universal since it states: "*It is merely a reminder for the whole world.*" The reason it was revealed in Arabic is explained in the Qur'an: "*And we never sent a messenger save with the tongue of his folk.*" Hence, the very

verse used to justify the belief that the Qur'an was revealed in Arabic implies an obligation to translate and transmit its message to non-Arabs. The main reasons for the disapproval of translation were that it might be used in prayer, might be taken as the inspired version, and might even replace the original. Translation is permitted for the purpose of explaining the meaning of the text to non-Arabs. However, for liturgical and non-liturgical purposes, it has to be recited in its original form (Poonawala 1990).

The *sunna* consists of the words and the deeds of the Prophet that were subsequently recorded and collected. It is second to the Qur'an as a source. Six canonical collections, namely, the *Sahihs* of Bukhari and Muslim and *Sunans* of Abu Dawud, Ibn Maja, Tirmidhi, and Nasa'i, compiled during the latter half of the ninth century, became most authentic among the Sunnis. Although the Shi'is have their own authentic collections of the traditions transmitted through their *imams*, it should be stated that a majority of those traditions share a common heritage. Two additional sources, namely, consensus of the community (*ijma'*) and jurisprudential interpretation (*ijtihad*) of the textual sources, especially the Qur'an and the *sunna*, were added later (Hallaq 2005).

Worldview

God. The doctrine about God in the Qur'an is rigorously monotheistic. God is one and unique; he has no partner and no equal. The concept of the Trinity is repudiated. There are no intermediaries between God and his creation that he brought into being by his sheer command: "Be!" He is the sole Creator, Sustainer, and Ordainer of the universe, wherein every creature bears witness to his unity and lordship. He is just and merciful; his justice ensures order in his creation wherein nothing is believed to be out of place. His mercy is unbounded and encompasses everything. His creation and ordering of the universe is viewed as an act of mercy. The God of the Qur'an, described as majestic and sovereign, is also a personal God and is viewed as being nearer to

man than his jugular vein, and whenever a person in distress calls him, he responds. Above all, he is the God of guidance and shows man the right way.

The depiction of God, wherein the attributes of power, justice, and mercy interpenetrate, is related to the Judeo-Christian tradition with certain modifications. It also provided an effective answer to the concepts of pagan Arabs who believed in a blind and inexorable fate over which man had no control. Awareness of God in Islam is primarily an awareness of obligation and accountability (Rahman 1980).

The Universe: In order to prove the unity of godhead, the Qur'an stresses on the design and order in the universe. Order is explained by the fact that every created thing is endowed with a definite and defined nature whereby it falls into a pattern. This nature allows everything to function in whole but sets limits to its power. The universe is viewed as autonomous, in the sense that everything has its own inherent laws of behavior, but not as autocratic because the patterns of behavior have been endowed by God and are limited. God alone reigns supreme in the heavens and the earth (Rahman 1980).

Man. The Qur'an is primarily concerned with man; hence, the universe is viewed as man-centric. The Judeo-Christian story about the creation of man from clay and the Fall of Adam is accepted, however, with profound differences. In contradistinction to the Christian doctrine of the Fall of Adam, the Qur'an states that God forgave Adam for his act of disobedience and sent him to this world as a prophet to provide guidance to the future generations. There is no concept of original sin and heavenly drama wherein God had to incarnate in the form of a person (i.e., Christ) and suffer to save mankind. The rest of nature obeys God automatically, but man alone possesses the ability to obey or to disobey. With the belief in Satan's existence and man's nature as frail and faltering, man's fundamental role becomes one of moral struggle. Man is viewed as "rebellious" and "full of pride," regulating to himself the attributes of self-sufficiency. According to the Qur'an, the being that became Satan had previously occupied

a high station but fell from divine grace by his disobedience to honor Adam. Since then his work has been to beguile man into error and sin (Rahman 1980).

Prophecy. In order to communicate the truth of the divine unity, God sent messengers to every nation in their native language. The Qur'an states: "*We never sent any messenger except with the tongue of his people.*" According to one tradition, there were 1,24,000 prophets. Judging from the accounts of the Qur'an, the record of mankind's accepting the prophet's message has been dismal. The messengers of God have been calling man back to God, yet very few have accepted the truth. When man becomes obdurate, God seals his heart; nevertheless, it is always possible for a sinner to repent and redeem himself by genuine conversion to the truth. There is never a point of no return, God is always willing and ready to pardon. Prophets are men specifically elected by God to be his messengers. Prophethood is indivisible and the Qur'an requires recognition of all prophets without discrimination. Yet, it states that they are not all equal; some are outstanding in qualities of steadfastness and patience under trial. Noah, Abraham, Moses, and Jesus were great prophets. God often vests them with miracles. All prophets are human and never divine (Rahman 1980).

Eschatology. On the Last Day, the world will come to an end and the dead will be resurrected and judgment will be pronounced on every individual in accordance with one's deeds. The Qur'an in general speaks of a personal judgment, but there are some verses that indicate the resurrection of distinct communities that will be judged according to their own books. Strictly speaking, there is no intercession, although God may permit that privilege to whom He wills. The notion that the Prophet, the imams, and *Awliya'Allah* (saints) can intercede on behalf of their followers developed quite early (Rahman 1980).

Myths and Legends. Islam, being a strict monotheistic faith, did not develop a proper mythology. However, early exegetes and popular preachers embellished the revelation and traditions through various stories, folktales derived

from the ancient Near East, especially from Judeo-Christian traditions. Legends were woven around the Prophet and members of his family. Sufis also played a role in attributing Qur'anic words with deeper allegorical and spiritual meaning and pious legends (Rahman 1980).

Islamic Religious Psychology

Amber Haque

Department of Psychology and Counseling, UAE University, Al Ain, United Arab Emirates

Related Terms

[Arab indigenous psychology](#); [Muslim religious psychology](#)

Description

The definition of Islamic religious psychology can range from “the study of human *nafs* (soul) from an Islamic perspective” to a more complex description, like the “study of manifestations of God in nature as reflected in the behavioral patterns of all living and nonliving organisms in all walks of their lives using the Islamic paradigm” (Vahab 1999). In Islam, human beings are said to

possess a dual nature, as they are both body and soul. However, the body is not as important as the soul because it is the soul that consists of the inner structure of personality, and body/matter is considered secondary to the spirit. The seat of knowledge in human beings is said to come from the metaphysical elements of the person, i.e., heart (*al-qalb*), soul (*nafs*), spirit (*ruh*), and intellect (*aql*). Islamic psychology or *Ilm al-nafsiat* (knowledge of the self) was studied by early Islamic scholars under the umbrella of Islamic philosophy or *falsafa*. The field does not exist today as a formal or independent discipline, but there are efforts among Muslim psychologists to revive this discipline (Haque and Mohamed 2009).

Self-identification

Science

Scholars who study Islamic religious psychology under the umbrella of Islamic philosophy do not claim it to be a science. However, a growing number of Muslim psychologists are now using experimental methods to discover relations among variables, e.g., effects of *salah* (prayers) on anxiety, and there is a growth of new scientific journals covering this research. In North America alone, two such journals are *American Journal of Islamic Social Sciences*, which started in the 1970s, and *Journal of Muslim Mental Health* launched in 2006. There is a growing concern among Muslim psychologists who studied mainstream psychology to increase the use of reliable, valid, and culturally sensitive instruments for measuring Islamic religiosity in order to make the discipline scientific (Ahmad and Geilen 1998).

Religion

The discipline is not considered religion, but it does cover many religious concepts including Islamic metaphysics, Islamic ethics, dimensions of human nature, study of the nature of human soul, Islamic spirituality, etc. Islamic scholars who are not psychologists may, however, consider the study of the *nafs* or soul as a branch of Islamic religion or Islamic philosophy.

Characteristics

The discipline is as old as the Islamic religion and was studied extensively over 1,000 years ago. Many of its concepts are unknown in the western world but relevant and meaningful for Muslims the world over. Its distinctiveness lies in its unique ethical, spiritual, and legal character and in its potential for contribution to the mainstream psychology.

Relevance to Science and Religion

For Islamic psychology, science and religion are intertwined and all scientific inquiries and observations should lead to confirmation of the existence of God and the need to follow the Islamic religion. It may be proper to say that science is viewed from a metaphysical angle and Muslim psychologists attempt to do scientific research using the principles of critical thinking but without compromising their faith in their religion.

Sources of Authority

The driving force behind psychological inquiries is the Qur'an, which addresses many issues related to human existence including human nature and other topics of psychological interest and invites human beings to reflect on these notions. Muslims consider the Qur'an as words of God and do not question its authority. Another trustworthy source of knowledge for Muslims is the *Sahih Hadith* (or verifiable) sayings and traditions of Prophet Muhammad. Also, books written by certain Sufis, saints, and scholars over the centuries have been a source of knowledge for Muslim religious psychologists. Muslims believe that the knowledge generated by these scholars was divinely inspired and so would constitute authentic knowledge.

Ethical Principles

The field is guided by the principle that to understand oneself and others is a moral obligation and

all knowledge ultimately points to the reality of One God. Human beings are granted the faculty to discern God's will and have the moral responsibility to submit to God and follow Islam. All actions and endeavors of a Muslim including his/her educational pursuits and intellectual inquiries are ideally dictated by this basic ethical principle.

Key Values

The key values are those that are inherent in the Islamic religion. It is important to realize that life has meaning and it should serve the purpose laid out by God Himself. Muslims look at the transcendental values that govern the transitory life of this world. Seeking knowledge and purifying one's lower self are the basis for gaining knowledge of others, the environment, the nature, and the hereafter (Rahman 1980).

Conceptualization

Nature/World

Nature came into existence by the command from God, and it is God Himself who manages the affairs of the universe. There is an integral view of nature, which sees the flow of divine grace in the arteries of cosmic and natural order. The nature/world is finite, however, and will eventually come to an end.

Human Being

Human beings are distinguished from other creations in that God breathed His own spirit into "man" and sent him to the earth as His deputy in order to do good in this world and establish God's will. Humans possess *fitrah*, which is the primordial faith implanted into them by God Himself. *Fitrah* entails original goodness, and human beings were created pure and sinless (Mohamed 1998). Values such as justice, mercy, patience, forgiveness, etc., are intrinsic to the human potential. When humans deviate from their *fitrah*, suffering and psychopathology may emerge. Psychopathology also occurs when humans are unable to control the various levels of their self. Human beings are distinguished

from the *jinn* or genie who have impact on the psychological well-being of a person. The *jinn* are beings created with free will, live on earth, but are invisible to the human eyes in their normal state (Philips 2002). From the Islamic perspective, both men and women came from a single soul and neither is inherently or automatically better than the other. It is only their deeds that differentiate them in this way.

Life and Death

From the Islamic religious perspective, God is involved in the creation and functioning of a human life and has also decided the length of one's life in this world. God also created everything for the service of human beings. Life and death are part of a divinely mandated plan that all creations are subjected to. For Muslims, life for humans is a series of tests whether or not they appear related to us individually. Death is just an end to this worldly life and a beginning of the afterlife. After death, the body may decay, but the soul will not, and each soul will be judged on the basis of its action in this life. It will also be rewarded or punished in the next life accordingly.

Reality

The central theme is *al tawhid* or oneness of God, under which all concepts are viewed, including reality, which comprises of the Creator and creature. These two orders are absolutely disparate and must not be confused with one another. Islam emphasizes the faculty of understanding, asking human beings to know that the divine will is understandable through the observation of creation and that the workings of the cosmos are purposive. Everything in this universe and beyond is meant to fulfill a certain universal purpose, and in it the will of the Creator is always realized. Through mindfulness, one gets to the point of being able to see this reality. This is similar to empirical science, except that its focus is not confined to the physical world but reaches the domain of the ultimate reality.

Knowledge

Knowledge in Islamic religious psychology refers to a conceptual understanding of

metaphysical terms like the *nafs*, *qalb*, *ruh*, *aql*, etc., and their influences on human behavior and thought processes. Knowledge of the self and human *fitrah* and knowledge of human beings as a microcosm of the universe and as a part of Divine Plan is essential in understanding the role and purpose of human beings in this physical world. Scientific knowledge is highly encouraged because with sincere reflection would bring oneself closer to God.

Truth

Truth or "*Haqq*" is often termed *lubb* or kernel in Islamic terminology. Those who possess the kernels know the truth, thus the Sufi adage: "to get to the kernel you have to break the shell." In other words, what appears "scientific" may not be the truth, and one has to dig deeper into the metaphysical realm to get to the core of human personality. The term personality is used here interchangeably with terms like *nafs* and soul, which reflects itself in an individual's psychological characteristics.

Perception

The physical senses are meant for purposes of physical survival but are unable to convey spiritual truths. Islamic religious psychology encompasses all sources of perceptual influence including unobservable phenomena like spiritual truths. However, developing a capacity to see within and beyond requires reflection, patience, and endurance and a taming of the brain so it does not interfere in the perceptual process (Wilcox 1995).

Time

The concept of time is unique in that the history does not exist in any real sense. The past is not a tale of the ancient but living truths carrying real meaning for the present. History is important in that it helps to create a total picture of the events that would ultimately lead humans toward ultimate knowledge and truth.

Consciousness

Our consciousness is constantly affected by our bodily functioning, the people around us, and the environmental forces. Our personal

consciousness, however, is not capable of representing but only a small portion of all this because our senses cannot detect many energy forms affecting our body and mind. As consciousness depends on and reflects one's needs and desires, our ordinary consciousness may be an illusion based on our sensory input. True consciousness cannot be attained through sensory modalities. One has to develop the "senses of the soul" to experience reality, which does not exist in the brain's biocomputer but in the electromagnetic fields around us and in interacting with our receptive capacities. The electromagnetic elements are those traditionally perceived as "spiritual" within an Islamic worldview.

Rationality/Reason

Reason helps us understand and know ourselves and the things around us. It is only through reasoning that one can attain proper knowledge and guidance in order to establish an ideal society on earth that will reflect God's will for humanity.

Mystery

Islamic religious psychology is complex and much of it is not well understood, e.g., the concepts of Islamic metaphysics, spirituality, fatalism, etc. Such religious concepts that appear a mystery are explained in Islamic religious literature but largely untouched by Muslim psychologists because of their training in secular psychology and also because most scholarly texts exist in Arabic language, not commonly known by the majority of Muslims around the world.

Relevant Themes

According to Islamic religious psychology, the notion of "sacred science" (Nasr 2001) is especially relevant for this discipline because natural science is based merely on human sensory perceptions and cannot get to the esoteric knowledge needed to understand the ultimate reality. A keen interest in the "unseen" and in eschatology is needed because of the metaphysical nature of (the discipline), i.e., Islamic religious psychology. Delving deep into Islamic science developed

by Muslims from second Islamic century onward is crucial because it addresses the nature of phenomena, causality, and relationship between various forms of objects based on Islamic worldview and rooted in concept of Unity of God.

Jewish Renewal Movement

Melissa Raphael
Department of Humanities, University of
Gloucestershire, Cheltenham, UK

Now known as Aleph, Jewish Renewal is a trans-denominational movement grounded in Judaism's prophetic, spiritual, and mystical traditions with the aim of political, ecological, and ultimately cosmic healing (in Hebrew, *tikkun olam*).

Conservative Judaism is a North American denomination dating from the early twentieth century that is more adaptive to modern living than Orthodoxy but less than the more liberal Reform movement. Halakah (Jewish law) is generally binding on Conservative Jews but is not considered to be of wholly supernatural origin.

The Haggadah is the text that sets out the order of the Passover Seder and is read communally at the Seder table.

Judaic Studies

Frederick E. Greenspahn
Gimelstob Eminent Scholar and Prof. of Judaica,
Florida Atlantic University, Boca Raton,
FL, USA

Related Terms

[Jewish](#); [Rabbinic tradition](#)

The relationship between Judaic Studies and science is complex. In part, this is because these are both umbrella terms, which embrace several discrete fields of study. Not only must one take both the natural and the social sciences into account, but even the humanities have, at times, espoused scientific methods and ideals. Further complicating the situation are the interconnections between Judaic Studies and the Jewish religion. Although the two are conceptually separate, many academic practitioners, as well as the institutions in which they work, are deeply committed to and involved with Jewish practice and beliefs. As a result, Judaic Studies scholars are often concerned with Jewish life, and their research is sometimes invoked and even sponsored by the Jewish community for which it has direct bearings.

The “scientific” study of Jewry traces its roots back to the early part of the nineteenth century, when a group of young Jews organized the Verein für Kultur und Wissenschaft des Judentums in Berlin. Although this was largely a response to the pressures of modernity, it also drew on long-standing Jewish impulses. The rabbinic tradition, which has been the dominant form of Judaism for nearly two millennia, places a high value on learning, even though the founders of *Wissenschaft* rejected the ways in which that impulse had been carried out. In fact, they regarded Judaism as a moribund tradition, which could be modernized by making it more *wissenschaftlich* (scientific). As Heinrich Heine, who was a member of the Verein, explained, the *Wissenschaft des Judentums* movement sought to reconcile “historical Judaism with modern science (*Wissenschaft*)” (Meyer p. 173), which he saw as coming into dominance. Or, as Leopold Zunz, the Verein’s leading figure, put it, “Only through science (*Wissenschaft*) can we obtain for Judaism the status and appreciation which it deserves and gradually arouse and unite all the better forces in Israel” (Meyer p. 175). Hence, their choice of the designation *Wissenschaft des Judentums*, although that name was not adopted until 2 years after the group’s creation in 1819. (It endured until 1825.)

Neither Judaism nor its intellectual tradition has historically been hostile to science. To the contrary,

Jewish tradition has at times claimed credit for inventing various scientific endeavors while, at other times, encouraging practitioners to take advantage of gentile insights. The Bible describes ancient Israel’s King Solomon as a master of natural science (1 Kgs 5:12–13 = ET 4:32–33), and scientific knowledge plays an important role in Talmudic discussions. One reason for this is the nature of Judaism, which dictates much of daily practice. As a result, one must understand animal anatomy in order to enforce Jewish dietary laws and be familiar with female physiology in order to carry out the principles of ritual purity. Over time, astronomical techniques came to be a valuable tool for calculating the calendar, leading the Talmud to restrict calendric decisions to those who possess the requisite mathematical skills.

These interests broadened during the Middle Ages under the influence of philosophical rationalism and Islamic models, which themselves drew on the Greek scholarly tradition. Many of the great medieval Jewish philosophers were physicians or astronomers, who had been trained in Aristotelian science. Thus, scholars such as Moses Maimonides offered striking observations about human physiology (noting, e.g., the Fallopian tubes), while Saadia Gaon contributed important insights into Hebrew linguistics. The latter field became highly developed within the Sephardic tradition, especially as a result of Judah Hayyug’s recognition that Hebrew words are based on three letter roots, which opened the way to exploring the relationships between different words and grammatical forms while facilitating the use of evidence from other Semitic languages.

Jewish interest in the sciences, and particularly medicine, expanded during the Middle Ages. Historians have subjected Jewish involvement in these fields to particularly close scrutiny, noting the existence of relationships with non-Jews. For example, Joseph Solomon Delmedigo, a seventeenth-century rabbi, mathematician, philosopher, and doctor, studied with Galileo. Similar interests have continued to the present day, with Jews playing a prominent role in the development of modern science, as dramatized by the prominence of such figures as Albert Einstein and Jonas Salk. In fact, one

third of all American Nobel prize winners in science have been Jewish.

Scholars have speculated as to the reasons for this phenomenon. In the early years of the twentieth century, Thorstein Veblen pointed out that, alongside the rabbinic tradition's emphasis on mental acuity, Jews' liminal social status strengthened both their tendency toward skepticism and their drive to go beyond the conventional, important factors in scientific research. The exclusion of Jews from many European universities may also have stimulated their gravitation toward newly developing fields, such as the sciences. The fact that these disciplines were not professionalized until the nineteenth century made them an attractive vehicle for social acceptance, although many nineteenth-century Jewish scientists converted to Christianity in order to gain access to universities where they could achieve their professional goals.

Conversely, scientific competence has sometimes facilitated specifically Jewish endeavors. For example, Chaim Weizmann, the first president of modern Israel, was a chemist, whose work on acetone gained him access to and the respect of the British government; that, in turn, contributed to British support for the Balfour Declaration. For both political and cultural reasons, science continues to play an important role in Israeli culture to this day. Not only is it home to the prestigious Weizmann Institute in Rehovot and the Technion in Haifa, but also numerous high-tech companies, 63 of which are listed on the NASDAQ, more than those from all of Europe, Japan, South Korea, India, and China combined. Although that nation's military and economic needs play a major role in this, so does the high value Jewish culture has traditionally attached to the sciences.

Cultural and social historians have explored the response of traditional Jewish thinkers to modern scientific developments, particularly those posed by astronomy (heliocentrism), biology (evolution), and geology (the age of the world). Significantly, these responses have followed patterns that were already laid out in the Middle Ages. Following the lead of Judah HaLevi, who rejected the possibility that anything in the Bible could contradict reality, traditionalists, for whom the

implications of emerging scientific ideas could be threatening, especially to the biblical miracles, sought ways to harmonize those accounts with their understanding of nature (concordism). Others, such as Maimonides and Levi ben Gershon (Gersonides) who accepted the authority of empirical observation, interpreted the Bible figuratively. Finally, there were still others, such as Judah Loew (the Maharal of Prague), who insisted on the separation of religion and science. This latter point of view, which can be traced back to antiquity, has made it possible for even religiously conservative Jews to engage in scientific endeavors without having to worry about the theological implications of their findings. The Association of Orthodox Jewish Scientists was formed in 1947 to address apparent conflicts between scientific findings and traditional beliefs as well as provide a setting for Jewish scientists to discuss common concerns.

All of these approaches have persisted into modern times. Alongside religious conservatives who reject any challenge to tradition, there are Jewish scientists who defend traditional teachings, albeit in sometimes nontraditional ways. For example, Immanuel Velikovsky's theory of catastrophism was, at its base, an attempt to defend the Bible's historical claims, albeit at the expense of its theological message. Although his views did not attract significant support, Velikovsky, who knew both Sigmund Freud and Albert Einstein, was offered the presidency of the Hebrew University. *The Bible Codes*, which was developed by Eliyahu (Ilya) Rips, a Soviet-born Israeli mathematician, reflects a similar dynamic in its effort to affirm the Bible's validity by finding hidden meanings in its letters. At the same time, many of the scientific community's most ardent opponents of traditional religious ideas, such as Carl Sagan and Steven Weinberg, have come from Jewish backgrounds. Concurrently, Judaic Studies scholars such as Richard Elliott Friedman, a biblical scholar, and Daniel Matt, a leading figure in the study of Jewish mysticism, have tried to harmonize traditional teachings with modern scientific insights by linking their respective fields to the Big Bang theory. Nor should one ignore the role of Jewish mysticism (kabbalah), which emphasizes the effect that human behavior can have on the

universe, in the development of modern science, especially as mediated by figures such as Isaac Newton and Gottfried Leibniz.

One motivating factor in the development of Judaic Studies during the nineteenth century was the fact that university level study of Judaism had previously taken place in theological settings, where it was largely under the direction of Christian Hebraists and theologians who saw Judaism as either preparatory to or a foil for Christianity. Thus, the historian, Heinrich Graetz observed, “The great question today is, will Judaism survive or disappear? For I regard it as disappearing if it is christianized, or as Heine says, if it spins the fringes of its prayershaws from the wool of the Lamb of God” (Schorsch, p. 279). Some of the founders of the Wissenschaft movement hoped to create a Jewish theological faculty at a major university to counteract the exclusion of ancient Israel from the study of antiquity (*Altertumswissenschaft*). They intended to study Jewish civilization using the same tools that were applied to other ancient cultures. To do that, they invoked the then prevalent philological approach, compiling scientific editions of important texts from which they hoped to draw contextual and comparative conclusions. In 1862, the Mekize Nirdamim (literally, “Wakers of the Sleeping”) society was established in order to publish hard-to-find medieval works. That led some scholars, such as the prominent Kantian philosopher Hermann Cohen, to criticize Wissenschaft for its “antiquarian” cast (Schorsch, p. 334).

When they did not find positions in German universities, several of these early figures in the field joined the faculty of Breslau’s Jüdische Theologische Seminar, which was established by Zacharias Frankel in 1854, making it, in one scholar’s words, “a tiny haven for a handful of frustrated Jewish academics” (Schorsch, p. 62); others were attracted to Berlin’s Hochschule für die Wissenschaft des Judentums. They also created several scholarly journals, including the *Monatschrift für Geschichte und Wissenschaft des Judentums* (1851–1939) and the *Revue des Études Juives* (1880–), which is published to this day.

By the early part of the twentieth century, the center of Judaic Studies had begun to migrate to

the United States and Israel along with the Jews who were leaving Central and Eastern Europe at the time. This demographic shift was signaled by the publication of the 12-volume *Jewish Encyclopedia* (1901–1906). Barely two decades later, the Institute of Jewish Studies was established at what would become the Hebrew University in Jerusalem. In addition to laying the foundation for what are now the field’s dominant centers, these events heralded processes that would culminate in the professionalization of Judaic scholarship.

Accompanying these geographic and institutional changes was a methodological shift from text study to history, a focus which was rooted in medieval works such as Azariah de Rossi’s *Sefer Me’or Einayim*. That required a more descriptive approach to the subject matter in place of the earlier prescriptive attitudes. No longer could one kind of Jewish activity be privileged over others; instead, everything Jewish was to be taken into account. As the nineteenth-century Italian scholar Samuel David Luzzatto put it, paraphrasing the Latin dramatist Terence, “nothing Jewish is alien to me” (Luzzatto, Iggarot, vol. 6, p. 780). Still, the field retained its apologetic edge, as is evident in its early tendency to avoid subjects such as Jewish criminal activities.

During the latter half of the twentieth century, the field expanded dramatically, gaining recognition in American universities alongside the study of other previously ignored groups, such as women, ethnic minorities, and lesbian, gay, bisexual, and transgendered people, thereby effectively achieving the goal that the field’s founders had set a century earlier. American Jews furthered this process by providing financial support for both positions and programs as a way of ensuring Jewish integration into American society and an expression of their growing pride and confidence. One by-product of this process was the establishment of several scholarly societies, including the Jerusalem-based World Union for Jewish Studies (1947) and the American Association for Jewish Studies (1969), as well as several academic journals.

This new setting exposed Judaic Studies to a variety of academic approaches and attitudes

which it, in turn, absorbed. Like many other fields, it also became increasingly specialized. No longer was it confined to texts and history, nor did practitioners need a broad Judaic background; instead, they might be trained in any number of specialties, such as literature or linguistics, often at secular institutions. These processes fueled the field's expansion and fragmentation with regard to both the topics covered and the backgrounds of those involved. It now includes many scholars whose expertise is limited to specific segments of the Jewish experience rather than Judaic Studies as a whole, while others, whose academic interests lie in areas unrelated to Jewish culture, apply their skills to issues relating to Jews and Judaism. There are also several non-Jews.

The impact of these changes has been particularly noticeable in the social sciences, which came to be an early component of Judaic Studies under the influence of scholars such as the historian Simon Dubnow and the folklorist Joseph Jacobs. Anthropological, geographic, and demographic topics were subjected to academic scrutiny in the late nineteenth century. For example, it was during this period that Berlin's Bureau für Statistik der Juden was created. Since then, demographers have tracked the growth and changing composition of the Jewish population around the world. Their work is often supported by local and national Jewish organizations, which use its findings to develop political policies and social services. Scholars have also collected cultural and folk customs, while examining the underlying dynamics of various religious practices, including the Jewish dietary laws, and the ways in which Jewish identity is determined and expressed. The consequences of these studies can be problematic. For example, Jewish anthropologists participated in that field's efforts to identify Jewish racial characteristics, an endeavor which correlated with the emergence of Nazi Germany's racial policies, even as it was being challenged by Franz Boas, the founding figure of American anthropology. Ironically, such views also led Adolf Hitler to reject the utility of what he termed "Jewish physics," forcing many Jewish scientists, such as Fritz

Haber, a Nobel prize-winning chemist who had converted to Christianity and played a critical effort in the German effort during World War I, to leave for other countries.

The discovery of new sources has enhanced research into the diverse manifestations of Jewish culture. The most dramatic examples have resulted from archeological excavation. The Dead Sea Scrolls, which first came to light in 1947, illustrate the value of such material for providing insight into previously unknown groups, thereby demonstrating the diversity of Jewish culture in periods that were thought to be well understood. However, not all such discoveries came about through excavation. In 1896, thousands of texts were found in the storeroom (*genizah*) of a Cairo synagogue. These cast light on any number of medieval Jewish customs and practices, while providing entree into the lives of ordinary Jews whose experience might otherwise have escaped our attention. Copies of some of these documents were subsequently found by archeologists among the Dead Sea Scrolls at Qumran.

Such research has contributed to the expansion of interest to include less familiar groups and practices that lie outside the "mainstream" Ashkenazi (Central and Eastern European) Jewish communities. For example, anthropologists now study any number of communities that were previously ignored. These include numerically, geographically, and ideologically "marginal" groups like the Karaites, marranos (*conversos*), crypto-Jews, Jews for Jesus, and Jewish Buddhists (JuBu's). At the same time, researchers in the "hard sciences" have begun to apply their tools to the history of Judaism and the Jewish community, including Jewish population genetics. Thus, geneticists evaluate the claims of heretofore ignored communities, such as the African Lemba, to Jewish ancestry as well as the validity of religious traditions about the genetic lineage of priestly status (*kohanim*). One outcome of this effort has been the Jewish HapMap project, based at the Yeshiva University and New York University medical schools, which is working to map the Jewish genome.

Because of their long tradition of in-marriage, Ashkenazi Jews have been a particularly valuable

resource for genetic research by both scientists and the Jewish community, with particular attention directed toward finding markers of distinctly Jewish diseases. Concurrently, academically trained and employed Jewish religious authorities, such as J. David Bleich, Elliot Dorff, Immanuel Jakobovits, and Moshe Tendler, have addressed the many challenges posed by modern science, particularly in bioethics, while Jewish scientists seek solutions for modern religious problems.

Modern technology has provided valuable tools, which can facilitate religious observance; for example, timers make it possible to turn appliances on and off without violating religious proscriptions. Such practices can also stir debates, as happened when the Conservative movement determined that driving to synagogue was permissible on holy days and Orthodox authorities allowed the use of appropriately equipped elevators on the Sabbath. Some have even tried to breed the red heifer, which the Jewish tradition teaches is necessary for the restoration of certain rituals (see Numbers 19). Meanwhile, the Internet has become a valuable tool for both communication and the dissemination of information, with some seeing it as a metaphor for more ancient modes of Jewish discourse.

Collectively, these efforts demonstrate the continuing vitality of the Wissenschaft des Judentums' project of using scientific scholarship to modernize Judaism itself. In so doing, however, they also demonstrate the persistence of the religious dynamic that underlies much of Judaic Studies and the corollary observation that the distinction between Judaism and Judaic Studies is not as hard and fast as it has sometimes been thought to be or, probably, ever was.

Judaism

Leonard Levin

Jewish Theological Seminary of America
South Orange, New Jersey, USA

A religion grounded in the ethnic-cultural tradition, firstly of the nation of Israel (from approximately 1300 BC to 586 BC), then subsequently of the people identified as “Jews” (Judah/Judea, from 586 BC to the present). The content of Judaism is formulated in the canonical texts of the Hebrew Bible (coterminous with the Christian “Old Testament,” though ordered differently) and the Babylonian Talmud. Since the nineteenth century, Judaism has been defined variously by its denominations, principally Orthodox, Conservative,

Reform, and Reconstructionist. All these denominations agree in affirmation of monotheism (belief in one God) but there is considerable leeway as to the definition of “God.” They also agree in the calendar of major holidays. They differ considerably as to the degree of applicability of the traditional Jewish law (*halakah*) based in the Talmud, and as to the degree of belief and manner of interpretation to be accorded the traditional narratives recorded in the canonical texts (though all except the ultra-Orthodox agree on understanding the latter in the light of contemporary historical scholarship).

Related Terms

[Jewish culture](#); [Jewish religion](#); [Philosophy and way of life](#)

The term “Judaism” encompasses more than religion; it names the complete culture and civilization of the Jewish people. Through the course of time that civilization undergoes dramatic changes, including changes in dominant scientific models in the broader civilization in which Judaism is a subset. This encyclopedia entry traces changes in Jewish thought in correlation with changes in scientific thought. At the most general level, there are five periods of cultural change so radical that new types of Jewish literature and new forms of communal identity emerge. There are several different ways to classify these periods, but for our purposes, where the emphasis is on the mutual impact of science and Judaism, the periods are (1) Biblical Judaism, (2) Classic Rabbinic Judaism, (3) Early Medieval Judaism, (4) Late Medieval Judaism, and (5) Modern Judaism.

1. The dominant culture of the competing Mesopotamian and Egyptian civilizations deeply influenced the creation of what became known as the Hebrew Scriptures (between the twenty-first century BCE and the construction of the second Judean temple in 515 BCE). The opening chapters in the book of Genesis, in particular, lay out a universal world and life view that contextualizes the history and legal system of the Jewish people that occupies the central content of this sacred anthology. (See “▶ [Creation and Science in Judaism](#)” and “▶ [Redemption and Science in Judaism](#).”) The counterpart to scientists in the narrative are called “sages” or “wise men” (*chakhamim* in Hebrew). They are both Jewish and non-Jewish. The kind of science they reflect in general is practical rather than theoretical. So, for example, Pharoah can summon his “magicians” (*chartumim*) to reproduce at least some of the early plagues that God visits on Egypt by the hand and rod of Moses (Ex 8:14) and Bezalel is said to be filled with “the spirit of wisdom (*chakhmah*)” because of his skills in molding precious materials (gold, silver, and copper) into utensils for the sanctuary. These precursors of Jewish scientists are really, in modern terminology, craftsmen and technicians. In contrast, those who receive

knowledge of the universe – who believe they know how the world began at creation and how it will end in redemption – are a different sort of men, called “prophets,” who receive their wisdom by direct communication from God.

2. The Judaism of the Bible undergoes radical transformation as the civilizations of the Egyptians and the Mesopotamians are replaced by a new dominant culture of the imperial Greeks and then the Romans, whose conquest of the Near East stimulates the development of both early Christianity and classical rabbinic Judaism (from the beginning of the Greek conquest of Persia and the Middle East in 334 BCE through the end of the reign of the Saboraim over the exiled Jewish community in Babylonia in 540 CE). At this stage the term that will come to mean scientists (“chakhamim”) is associated with rabbis. The skill of these wise men is that they have inherited a tradition that enables them to infer the true and far-from-obvious meanings of the Hebrew Scriptures. But more than imparting knowledge, these men claim that they can impart wisdom (sofia). They are truly “lovers of wisdom” (philosophers) whose truths enlighten a path that leads directly to personal and collective happiness.

There are no rabbinic texts specifically dedicated to the study of nature as nature, which in general was looked upon as “external” or “foreign” wisdom, which is to say a form of wisdom removed from the Jewish wisdom of the rabbis. However, the separation was more theoretical than practical, since rabbinic texts such as the Jerusalem and Babylonian talmuds as well as the various collections of midrash (direct rabbinic conceptual commentaries on specific biblical texts) contain much that we would identify as “Greek” wisdom. Notable examples are readily at hand from mathematics, astronomy, natural history, and medicine.

An example from mathematics is the determination of how far an “eruv” extends, which is a virtual enclosure beyond which a person may not travel on the Sabbath. A second

equally important example is fixing the calendar. Similar examples include methods for calculating mixtures of grain and the holding capacity of a ritual bath. In a similar vein the rabbis calculate the ratio of the circumference of a circle to its diameter in order to discuss legal questions concerning the distance around a sukkah (ritual booth). Similarly, in the case of astronomy the determination of spherical cycles and planetary courses is most often connected with determining the liturgical calendar. One example from natural history is speculation about the relative life expectancy of diverse kinds of animals, including serpents, bears, dogs, and cattle. Finally, in terms of medicine, there are several thousand examples (N Efron, 55) because many rabbis (including Maimonides) were physicians. Passages include discussions of human anatomy and physiology, gynecology and obstetrics, hygiene, mental illness, and aging.

All of these examples of science in the classical rabbinic texts are *prima facie* “unsystematic” (*ibid.*) because they appear in the context of the discussion of either the meanings of the Hebrew Scriptures or discussions of Jewish law. But precisely because of this integration of scientific literature, the classical rabbinic literature exhibits an integration of science and Judaism that will subsequently decline, until it largely disappears completely in the modern period.

3. The new dominant culture of imperial Islam replaces the Hellenistic world in the lands surrounding the Mediterranean Sea (notably Egypt, North Africa, and Spain), extending from the establishment of the Ummayyad Caliphate, centered in Damascus Syria, in 661 CE, through the death of Moses Maimonides in Egypt in 1204, and classical rabbinic Judaism is transformed into early medieval Judaism. This transformation gives rise to a great deal of diverse rabbinic literature, including a standardized Jewish communal prayer books, major codes of Jewish law collected from a multitude of individual rabbinic legal decisions (referring back ultimately to

the Talmud and the Mishnah), as well as major philosophical commentaries on the conceptual meaning of the Hebrew Scriptures. Besides general works of theological philosophy by Platonists, Aristotelians, and Atomists, we begin to see some empirical studies of the physical world in a thematic form rather than as scriptural commentaries. Notable examples are the mathematician Abraham Bar Hiyya (d.c. 1145) of Barcelona, the natural philosopher Abraham ibn Ezra (1089–1167), and of course the physician Moses Maimonides. Bar Hiyya wrote a distinguished treatise on geometry (called *Hibbur ha-Meshichah ve-ha-Tishoret* in Hebrew and *Liber embadorum* in Latin) which introduced to Europeans algebra as well as a solution to the quadratic equation. Ibn Ezra's *Sefer Ha-Ehad* (Book on One) deals with number theory, *Sefer ha-Mispar* (Book on Number) introduces the Indian decimal system, his *Keli Nehoshet* (The Brass Instrument) is a handbook on the use of the astrolabe, and several books on astrology.

The connection between the knowledge of nature and the attainment of the good life, between what we call "science" and "ethics," is spelled out explicitly by the rabbis of this period, building on the world view of the Greek Platonists, Aristotelians, and Atomists to explain the believed inherent connection between the two disciplines. For the Platonists, the dimly and fuzzily perceived objects of the senses are only suggestions of what truly is the object of knowledge – the clear and precise forms, the highest of which are Truth, Goodness, Beauty, and God, which are themselves identical. Hence, what science leads to is what we would call religion, the ultimate good of gazing into the light of the one and only absolutely real deity who is identical with truth, goodness, and beauty.

The world view of the Aristotelians is not identical but similar, and it ends up affirming the same overall view, viz., that there is only one ultimate object of knowledge, which is the same ultimate objective of religion, viz., to achieve oneness with God. In the Aristotelian

case, however, the nonmaterial forms that point to the immaterial deity are contained within the perceived objects as what defines them. The differences are important and they will become increasingly important in the early modern period when the Renaissance humanists will carefully examine and distinguish the different conceptual strains of learning past on through the Middle Ages. It will be at this time that the material atomism of the Stoics will be revived and, by the seventeenth century at least, become the dominant world view for all of science.

4. The decline of Muslim hegemony in the world of the Mediterranean Sea opens the door for a new religious and political empire, The Roman Catholic Church, and a new kind of expression of Judaism, the Kabbalah. This late medieval period extends from the second crusade beginning in 1147 to the expulsion of the Jews from Portugal in 1497. Arguably, the most important Jewish natural philosopher of this period was Levi ben Gerson (Gersonides) (Provence, 1288–1344) who wrote many books on astronomy as well as inventing the "Jacob's staff," which, prior to the telescope, was the most advanced mechanical aid for astronomers measuring relative distances of stars. His *Milchamot Adonai* (Wars of the Lord) was the most sophisticated application of Aristotelian philosophy to interpret Jewish faith doctrines devised in the period. In many respects, especially in terms of the values of clarity and precision, Gersonides' philosophy is the highest achievement of the middle ages. But in many other respects, this period marks the decline of rational thinking in the pursuit of knowledge. What replaces it in the devotion of the lovers of wisdom of the period was Kabbalah.

Arguably, the single set of events that contributed most directly to the decline of natural philosophy in favor of mysticism was the so-called Maimonidean Controversy. The heart of the debate that raged through Western Europe in the thirteenth and fourteenth century focused on censuring the

philosophical writings, the so-called Greek wisdom, of Moses Maimonides.

The issue was not, as it is often characterized, rationalism as opposed to irrationalism. While there were some who discounted Greek wisdom because it was Greek rather than Hebrew, the question was not whether or not non-Jews can have knowledge. Rather, it should be remembered that Jewish law obliges the Jew to do what is good and think what is true, and the obligation to know truth, at least with respect to Jewish law, applied only to Jews. Hence, the issue was not a limitation on who can have knowledge, but on for whom knowledge counts as a religious duty.

The more serious issue was with the perceived dangers in the pursuit of knowledge. Reason, so it was argued, when properly used will lead to truth. But nature does not yield her secrets without a struggle. There are many opportunities to err, and in this case, since the object of study is the creator and his creation, err is heresy. Hence, the study of natural philosophy (or what is close to what we today would call science) was radically restricted because it was considered dangerous.

The issue itself was subtle but the results of the debate were not. A virtual ban with threat of actual excommunication was placed on the study of the philosophical traditions whose origins lay in the preserved writings of Plato and Aristotle. The result was that while learned rabbinical scholars entered the fourteenth century armed with a reasonable acquaintance with the best of fourteenth century natural wisdom, by the seventeenth, eighteenth, nineteenth, and even twentieth centuries all too many of these rabbis continued to think about the natural world with fourteenth century minds.

5. Late medieval Christian Europe gradually transformed into modern Europe. From the perspective of Jewish civilization, this is the age in which (at least culturally) traditional rabbinic expressions of Judaism are transcended by liberal as well as secular expressions of Judaism. This modern period

extends from the birth of Nicolaus Copernicus in 1473 through the establishment of the Kabbalistic school of Safed in Palestine in 1532 to the present. It is this period that gives rise to multiple forms of liberal religious Judaism (including Reform Judaism, with its first synagogue in Berlin in 1847), initiates the scientific study of Jewish history (arguably with Heinrich Graetz's *History of the Jews*, completed in 1878), and marks the ascent in Jewish communal life of secular forms of Judaism (including Zionism, formally with the publication by Theodor Herzl of *The Jewish State* in 1896).

With the notable exception of Baruch (Benedict) Spinoza (1632–1677) most rabbis turned either to the intricacies of Jewish law for mental challenge or the imaginative cosmological reflections of the Kabbalah hoped for insight into the deepest secrets of empirical reality to know the deeper truths they knew that lay beyond the screen of the senses. The above description however should be qualified. The picture of a strict rationalism of natural philosophy and soft fuzziness of mystical imagination is too stark. The lines in reality were less clear. The use of reason itself always involves the use of the imagination, and imagination itself is subject to rational clarification. Even more specifically, men of the major figures whose scientific work brought on the modern age of reason were themselves deeply involved, or at least intrigued, by the Kabbalah. The list includes Francis Bacon and Isaac Newton as well as other notable members of the seventeenth century British Royal Society. Counted among the Jewish scholars who also bridged the gap between Kabbalah and natural philosophy were Rabbi Judah Loew ben Bezalel (the Maharal) (1525–1609), Moses Isserles (Rema) (c.1530–1572), Solomon Luria (1510–1573) (the chief rabbi of the academy of Lublin), David Gans, Joseph Solomon Delmedigo (1591–1655), Tobias Cohen (1652–1729), and many others.

It should be noted that the path of admission of European Jews into the university, the

modern institution that trained individuals to become academic professionals, was not at first open to Jews. The story is part of a larger story of very ambiguous relations between Jews and Christians throughout European history. Christianity began as an outgrowth of Biblical Judaism more or less parallel to the rise of rabbinic Judaism, which makes the two religions competing cousins at the very least (if not warring brothers). Jews in general play a critical role in the development of Christian European civilization, but within that civilization the Jew remains the perpetual outsider. The Jews more than any other people have been the permanent “other” to the Christians “we.” This story is exemplified in the relationship between the Jewish people and the European university, and it is dramatically accented in the way this history played itself in Germany, the most significant land of Jewish settlement in Western and Central Europe.

From the eleventh century on the Germanic lands housed a well-developed Jewish health-care system that included hospitals as well as professionally trained family dynasties of physicians. At the same time, Jews were also viewed as members of a different race, and this racism colored the otherwise high respect in which Jewish physicians were regarded for their comparatively exceptional skill in healing patients. By the beginning of the nineteenth century, the Jewish otherness gave rise to mass anti-Semitism, significantly directed against Jewish doctors and Jewish medicine. While at the same time there were other European Christians who acknowledged the humanity of Jews, particularly if they could overcome their “Jewishness,” and these more liberal Christians fought for the admission of Jews to German medical schools in the eighteenth century, 200 years later than Jews were admitted into medical schools in Italy. It was in the middle of the nineteenth century that Jews gained citizenship in the newly formed German nation, Jews in general gained admission to university academic

programs, and medicine in particular became the crowning achievement of the Jews integration into German (and European) civilization. However, the achievement was far from permanent. By the end of the nineteenth century there spread through Germany as well as other western European nations, both at the level of intelligentsia and the ordinary people, beliefs that Jews had special mental, spiritual, and even physical innate defects that separated them from the rest of civilization. It is this racism that culminated in the Nazi policies against all Jewish people in the 1930s and 1940s.

From the 1870s on Jews had flocked to the European universities where many Jews achieved distinction in many fields, including the sciences. But by the 1920s these achievements were being diminished as something Jewish that was inferior to the achievements of non-Jewish academics and scientists. Jews were seen to be “clever” but not really “intelligent.” And new sciences in particular, notably the Jew Einstein’s relativity theory in physics and the Jew Freud’s psychoanalysis in psychology, were dismissed from many European universities as illegitimate science because they were “Jewish science.”

By the nineteenth and twentieth centuries and the integration of Jews into the politics and culture of modern Christian Europe, there developed an increasingly radical separation between those Jews who studied the sciences and those Jews who studied Jewish texts. What is critical is, in consequence of the Maimonidean controversy, scientific subjects ceased to be considered Jewish. Instead, they were part of something called “general studies,” while in the non-Jewish world of western Europe “science” itself was separated from what was called the “humanities,” as increasingly into the twentieth century there developed a major intellectual and cultural gap between the sciences and the humanities. Jews actively participated in both groups, but rarely were there any cross-overs, particularly among rabbis who spoke

for Judaism and whose academic training increasingly was humanistic.

By the twentieth century, especially in North America, Jews played a dominant role in scientific life. The who's who of science names includes Jews like Richard Feynman, Carl Sagan, Stephen Jay Gould, Albert Michelson, Isidor Rabi, J. Robert Oppenheimer, Edward Teller, John von Neumann, Albert Sabin, Jonas Salk, Norbert Weiner, and Murray Gell-Mann to mention only a few of the most famous Jewish scientists. In these cases, we know about their contribution to science, but we know nothing about most of them as Jews, and from what we know from the few who actually wrote about their attitudes toward religion, we see that the level of sophistication of their thought about Judaism is in no sense comparable to their knowledge of science. In this sense, the twentieth century has been relatively unsuccessful in exhibiting any new forms of integration of Judaism and science, and that is not surprising given two factors in particular. One is the radical increasing separation between the two cultures of the sciences and the humanities with the classification of Judaism as a religious humanity. Two is the fact that few trained scientists are also rabbis or, to be more accurate, have anything approaching a professional knowledge of Judaism. It is too early to judge whether or not this separation will continue in the twenty-first century.

6. There is a sixth period that we could add to our list. Let us call it, for want of a better term, "post-modern Judaism." We characterized the modern period both in terms of the sciences and Judaism. The modern forms of science were Newtonian physics, Freudian psychology, Darwinian evolution in the life sciences, and Socialism in economics and politics. Similarly, we identified modern Judaism with liberal Jewish religion and secular nationalist Zionism. Post-modern, as the term is used here, means any expressions of science and Judaism that move beyond the limits of what we have called "modern." In this sense, Quantum Mechanics and Relativity in

physics, and physicalist reductionism in psychology are post-modern, as are various new twenty-first century models of economics and politics and new emerging forms of Jewish identity that transcend now classical models of Reform, Conservative, Orthodox, and Reconstructionist Judaism, as well as forms of post-Zionist Jewish secular identity. However, it is as yet too soon to characterize them. Many of them will fade from existence and even those who survive and prosper will be transformed in unending processes of change, for Judaism, like science, is not a static concept but a living entity.

Jungian Psychology

Carl Raschke
Department of Religious Studies,
University of Denver, Denver, CO, USA

An influential method of psychoanalysis developed by the twentieth-century Swiss clinician C.G. Jung that rejected Freud's pan-sexualism and emphasized the quest for universal archetypes of the unconscious manifested distinctively in dreams and myths. Jung was fascinated with Gnosticism, and developed both a psychological theory and a general philosophy that both he and his followers have regarded as "Gnostic."

Justice (Philosophically)

Michael Fuerstein
Department of Philosophy, Saint Olaf College,
Northfield, MN, USA

Introduction

In general terms, justice is the morally appropriate allocation of benefits and harms. Justice may concern the activity of political and legal institutions, social patterns of advantage and disadvantage, the disbursement of criminal punishment or reparations, the fairness of particular

interactions among persons, or the character traits of individuals.

Philosophical discussions of justice extend back at least 2000 years to the time of Plato and Aristotle, and the idea of justice is already evident in discussions of law in the third millennium B.C.E. The idea of justice – both in its substantive requirements and in its general subject matter – has been understood in extraordinarily diverse terms by an enormous number of theorists. By necessity, therefore, the discussion that follows will be highly selective, focusing on the most significant approaches to justice in the Western philosophical tradition.

Early Theories of Justice

The Code of Hammurabi

The earliest recorded discussions of justice feature legal codes of punishment that presage notions of fairness and reciprocity central to the notion's later development. Prominent among these is The Code of Hammurabi (eighteenth century B.C.E.), which offers up a series of social rules and prescribed punishments for various infractions, aiming to ensure that "the strong should not harm the weak." Some of these punishments present quite literal interpretations of reciprocity, as in the famous "eye for an eye" requirement: "If a man put out the eye of another man, his eye shall be put out" (no. 196). From this perspective, others seem to be vastly out of proportion with the crime perpetuated: merchants who sell stolen property are to be executed (no. 9), for example. Many of the punishments are clearly intended to provide compensation to victims: those who accidentally flood a neighbor's field, for example, are to pay the neighbor in corn for their lost crops (no. 55). In general terms, the laws embody the core ideas that (a) those who perpetuate unjustified harm on others become the proper recipients of some appropriate harm in return and (b) those who are the victims of unjustified harm are entitled, where possible, to compensation. In some form, both of these notions remain durable fixtures of theories of justice throughout the idea's history.

Plato

Whereas the earliest treatments of justice are principally codifications of rules and punishments, the Ancient Greeks began to offer a systematic approach to the philosophical questions surrounding justice, that is, those concerning its nature, proper subject matter, and the status of its requirements within a broader moral framework. The first such treatment comes in Plato's masterpiece, the *Republic* (ca. 360 B.C.E.), which is devoted to an investigation of justice in both the individual and the polity overall. Plato argues that justice in the polity concerns its ability to perform its characteristic purpose or function well. On Plato's view, that function is to serve citizens' diverse needs as well as possible, or, in his terms, to foster the greatest amount of "happiness." That aim is achieved, Plato argues, when all citizens are assigned to perform the role for which they are best suited, a claim that implies a highly regimented and hierarchical society: there are some who are, by nature, best suited to rule (the philosopher kings or guardians of the state), and there are others who are, by nature, suited to be ruled, and all individuals are defined by membership within a particular social class. Analogously, Plato thinks that just individuals are characterized by a harmonious division of labor among discrete parts of the soul: our rational soul must rule over our appetites and emotional impulses. In achieving this, Plato argues, we will be both good and happy.

The understanding of justice that we get in the *Republic* is notably anomalous in its avoidance of any systematic treatment of punishment or fairness. Plato's project is to describe the ideal person and the ideal polity. Although that tells us what a good world would look like, it does not tell us in any clear way what we – as citizens, criminals, or victims – are entitled to receive in return for what.

Aristotle

In contrast, Aristotle's account of justice builds naturally on ideas implicit in the early codes of punishment and anticipates more recent preoccupations with the idea of economic and contractual

fairness. Aristotle's primary discussion of justice comes in the *Nicomachean Ethics* (ca. 350 B.C.E.), where he distinguishes between what he calls "general" and "special" notions of justice. General justice corresponds to a broad notion of moral virtue that applies both to individuals who are disposed to act and think well, and to states that rule in service of the common good. Special justice, however, is a more specific notion that concerns the appropriate distribution of harms and benefits relative to a fair equilibrium. It is this latter notion that fits most transparently into the historical development of the idea up to the present.

Prefiguring a distinction that has ultimately become commonplace in discussions of justice, Aristotle divides the idea of special justice into two forms: justice in "distribution" and justice in "rectification." Justice in distribution concerns the fair allocation of goods or benefits held among the community, such as respect, honor, or property. Aristotle holds that individuals ought to receive in proportion to merit, where merit is a function of the individual's contribution to communal assets. Thus, citizens who contribute more to the prosperity of their society through their virtue or leadership qualities, for example, are entitled to a greater share of power and respect in return. Aristotle's notion of justice in distribution is thus compatible with substantial social and political inequalities so long as they are connected with proportionate differences in relevant merit.

Justice in rectification for Aristotle concerns the response to unjust transactions among individuals. An unjust transaction, on his view, is one that introduces inequality between the parties involved relative to their previous levels of well-being. If A steals from B, for example, then A receives a net gain from the transaction while B receives a net loss, thereby introducing inequality. Restoring equality, for Aristotle, can involve some form of reparations for the losses incurred by A as well as some form of harm inflicted on B to cancel out B's gains. However, Aristotle never specifies exactly what the standard of equivalency is for losses and gains, making it difficult to derive precise implications

from the theory. In very general terms, nonetheless, his view of corrective justice provides a very early basis for thinking about fair compensation and punishment.

Distributive Justice

In keeping with the division espoused by Aristotle, theories of justice are now conventionally divided into theories of distributive or social justice and theories of punishment. This section will discuss the former, and the next section will consider the latter. Theories of distributive justice concern the fair allocation of goods that determine the scope of individuals' basic opportunities and quality of life. Because economic goods (money and property) figure so centrally in this respect, theories of distributive justice have typically focused most centrally on them. Such theories may also nonetheless concern political rights, social status and opportunities, education, and healthcare.

Justice as Fairness: Rawls

Without question, the most influential theory of distributive justice in the past century has been that of John Rawls, and most contemporary philosophical discussions of justice are in some way aligned in support or rejection of Rawls's views. In *A Theory of Justice*, Rawls argues that a just scheme of distribution is that which we, as free, equal, and rational individuals, would choose behind a "veil of ignorance," that is, under conditions in which we did not know our class or social status, the extent of our natural talents and abilities, or the nature of our substantive moral beliefs. Because it models principles of justice as the result of an ideal choice situation, it fits firmly into the so-called "contractarian" tradition of thinking about political and moral arrangements developed in the seventeenth and eighteenth centuries by Thomas Hobbes, Immanuel Kant, John Locke, Jean-Jacques Rousseau, and others.

The rationale for the veil of ignorance is that, on Rawls's view, it provides a hypothetical model of perfectly fair conditions of choice. Hence, Rawls dubs his view "justice as fairness."

The result of choice under such conditions, Rawls argues, would be three principles:

- (1) Each person should have "the most extensive scheme of equal basic liberties compatible with a similar scheme of liberties for others."
- (2a) *The Difference Principle*: Social and economic inequalities should be structured so as to maximize the prospects of the worst-off members of society.
- (2b) *Fair Equality of Opportunity*: "Those who are at the same level of talent and ability and have the same willingness to use them should have the same prospects of success regardless of their initial place in the social system" (63).

Principle 1 embodies a very basic conception of equality that is present in more or less all notions of justice that follow the introduction of moral and political egalitarianism in the Enlightenment. The principle of fair equality of opportunity embodies the intuitive idea that it is unfair when our success in social competition is influenced by morally arbitrary factors and in particular our initial social standing.

The most natural interpretation of the difference principle is a taxation scheme in which the rich are heavily taxed to pay for programs and subsidies that benefit the poor. The limit on taxation of the rich, following the logic of the difference principle, is just that point at which their incentives to be productive are reduced enough so that tax revenue available to aid the worst off begins to decline. The difference principle thus embodies the idea that substantial economic inequalities are permissible just so long as the poor benefit from them. Under the familiar conditions of capitalist society, those benefits come in the form of extra incentives (in the form of wealth) for the most productive members of society to contribute as much as possible to net social wealth through profitable ventures and technological innovations. The difference principle has proven particularly contentious in contemporary discussions of justice, and the main objections to it will be addressed in the next two sections.

Egalitarianism

Egalitarianism with respect to distributive justice is the view that all citizens are entitled to equal shares of some basic set of social goods, though it is a matter of contention what, exactly, constitutes the social good(s) that should serve as the basic measure of equality. Prominent understandings of that measure have included resources, well-being, opportunity, capabilities, and others. Given the broad interpretability of the idea of equality, therefore, more or less all contemporary theorists of distributive justice are egalitarians in some form.

Perhaps the most straightforward understanding of egalitarianism proposes that all citizens should receive the same amount of financial and material resources. But this idea is problematic on a variety of grounds. For one thing, citizens may have different levels of need, and, in that case, equal resources would lead to highly unequal degrees of welfare. Karl Marx thus proposed, in his “Critique of the Gotha Programme,” that all should contribute “according to ability” and receive “according to need.” Marx’s view is thus emblematic of a left egalitarianism that rejects inequalities in human welfare stemming from economic inequalities and which denies that inequalities can be justified by reference to merit or productivity.

In contrast, within a Rawlsian framework, substantial inequalities in material resources persist, contingent on the fact that some are more productive and therefore benefit the worst off by improving net social resources. Rawls’s view thus embraces the capitalist idea that inequalities in human welfare are a function of incentives that make individuals more productive and that therefore benefit all. From a leftist egalitarian point of view, such inequalities perpetuate a social order in which those worst off are dominated and reward the selfishness of those who will only contribute their skills in return for a greater share of economic reward.

Libertarianism

Left egalitarians have a very weak view of property rights: our entitlement freely to hold and exchange goods is subject to the tight constraints of maintaining equality relative to need. Libertarianism, in contrast, holds a strong view of

individual property rights: individuals are entitled to keep whatever they can fairly acquire through their own merits or through free exchanges with other individuals. Robert Nozick, the most influential proponent of libertarianism, thus holds that a social scheme of distribution is just strictly insofar as it is produced through a sequence of fair acquisitions and free exchanges among individuals. Gross inequalities are therefore justifiable so long as they arise through a historical sequence that satisfies these conditions. Nozick criticizes Rawlsian and left egalitarian alternatives to libertarianism on the grounds that the redistribution (through taxation schemes) of justly acquired property is an infringement of individual rights. One important problem with this view, however, is that, as Nozick himself concedes, it remains highly questionable whether the historical chains of events through which present property holdings came about were just. A second important issue concerns the moral status of the differences in skill and fortune that allow some to acquire greater holdings than others. Rawlsians and left egalitarians view such differences as morally arbitrary and therefore incapable of justifying inequality.

Punishment

Punishment involves the infliction of some pain or cost on an offender for moral and/or legal transgressions. The Code of Hammurabi, considered earlier in this entry, provides an early example of social rules and the punishments that correspond to their violation, but does not offer a substantive account of the justification for punishment, or a conception of fair punishment. Justifications of punishment have been dominated by a dichotomy between consequentialist and retributive theories, and these are both considered below.

Consequentialist Theories of Punishment

Consequentialist theories of punishment hold that the justification of punishment is its tendency to advance morally good consequences, which we can generically characterize in terms of “the public good.” Though the notion of “public good” is

a matter of substantial dispute, all consequentialist theories are defined by their concern for the effects of punishment practices on future states of affairs.

The future effects of punishment are complex, but the most significant concerns of consequentialists are (a) the tendency of punishment to reduce the commission of moral harms by inspiring fear and fostering, through the public display of communal morals, the social embrace of a valid moral code, and (b) the tendency of punishment to reform offenders by facilitating the abandonment of morally bad beliefs and tendencies. Consequentialist theories take a different shape depending on how these different kinds of effects are weighted. A consequentialist who views deterrence as the most important effect is likely to recommend substantially harsher penalties, for example, than one who puts reformation at the center of the theory.

Consequentialist views confront a variety of significant objections. Among the most significant are those that focus on the idea of proportionality. Consequentialists are committed to endorsing extremely harsh penalties for mild transgressions, for example, just so long as doing so benefits the public through strong deterrent effects. Conversely, consequentialists are committed to mild penalties for extreme transgressions, just so long as the gains in deterrence or reformation achieved by stronger transgressions are small or negligible. In general terms, consequentialists have no intrinsic sense of fittingness in the assignment of punishments; rather, fittingness or proportionality is simply a function of anticipated consequences.

Retributive Theories of Punishment

In contrast to consequentialist theories, retributive theories hold that it is the fact that someone is the perpetrator of a particular type of offense, and only this fact, that is relevant to determining the pain or cost that is due to them. Any further consequences that arise from punishment – its deterrent effects, for example – are irrelevant to its justification. Retributivists have attempted to justify the view in various terms. On Hegel's influential view, for example, punishment

functions to “negate” the original transgression. Other proposals focus on the way in which justice restores to equilibrium the relative well-being of victim and perpetrator, or on the way in which punishment expresses a warranted emotional response to injustice.

Retributive theories avoid the particular difficulties with proportionality that consequentialists face insofar as the harshness of a punishment, on the retributive view, is strictly determined by the severity of the crime. But retributive theories, unlike consequentialist alternatives, have a more difficult time explaining why a particular punishment is warranted by a particular crime. Whereas the consequentialist can refer simply to the anticipated benefits of matching particular punishments with particular crimes, retributivists are burdened with the difficult task of explaining and interpreting their particular conception of proportionality. Aside from these difficulties, retributivism cannot account for many ordinary and seemingly essential features of our institutions of punishment, which provide a vital system of incentives for the regulation of social conduct. In abandoning consequentialist arguments, the retributivist cannot explain how our punishment practices should be adjusted in order to serve effectively as vehicles of deterrence, education, and rehabilitation.

Religious Convictions and Public Principles of Justice

As the preceding discussion reveals, ideals of justice are not only philosophical theories; they are also substantial proposals for the organization of social and political institutions. They also provide a basis from which to justify specific legal policy prescriptions on a broad range of social issues. At the same time, in contemporary pluralistic societies, citizens approach questions of justice from diverse religious and moral worldviews, many of which are incompatible in important respects. It is therefore essential for political communities to be able to address important questions of justice, as a community, in spite of such underlying disagreements.

In recent years, political philosophers have sought to develop a theory of “public reason”: an account of what kinds of considerations citizens are morally permitted to appeal to in deliberating about public (legally codified) matters of justice. On the dominant interpretation of public reason, developed by John Rawls, citizens should restrict themselves in deliberations about justice to considerations that are acceptable from all “reasonable” points of view. “Reasonable” citizens, on this view, are motivated by an ideal of fair cooperation with their peers and acknowledge their fallibility in debate. The motivation for this proposal is a classical liberal social ideal: in a free and egalitarian society, no citizens should be required to live under social arrangements that they cannot endorse from their own point of view.

As critics of this view point out, in ruling out reasonably contested views, we must effectively bar from public debate many principles that are essential to citizens’ understanding of themselves and the world. In this regard, religious citizens seem to be at a particularly grave disadvantage, because such a principle is likely to rule out much of what is essential to and distinctive of religious worldviews. Appeals to Scripture, to insights gained through revelatory experiences, or to the teachings of religious authority figures, for example, will all plausibly be ruled out of public deliberation. In place of these appeals will remain insights that can be justified through publicly verifiable experience and rational inference. The consequence is likely that our public understanding of justice will be shaped exclusively by secular considerations. Religious critics contend that this restriction ultimately amounts, itself, to a violation of religious and personal liberty. They have also argued that, in restricting ourselves strictly to uncontroversial premises, our discussions of justice will be narrowly limited to individualistic and materialistic considerations.

The challenge for religious critics of public reason remains the concern that if we fail to rule out controversial moral and religious ideals from our deliberations about justice, we will open the door to unacceptable forms of government coercion. The atheist who lives in a society in which biblical principles provide the public rationale for

justice, for example, plausibly has reason to feel alienated and disrespected by the prevailing social order. Notably, the same is true for other religious individuals who hold differing interpretations of the Bible or who view a different religious text as authoritative. From this point of view, religious citizens themselves have reason to endorse the standard interpretation of public reason as a principle that prevents others from imposing upon them a moral framework that they cannot accept.

Description

Kabbalah is a distinctive intellectual strand within Judaism that functioned as a self-conscious program for the interpretation of rabbinic Judaism. Rooted in esoteric speculations of the rabbinic period, kabbalah emerged in the Middle Ages as the theory and praxis of Jewish life that fathomed the depth of divine mysteries; charted the paths for interaction with God – including a mystical union with God; and harnessed divine energy for the redemption of the world. Although kabbalah viewed its

doctrines as timeless truths, first revealed by God in the creation of the universe, kabbalah was a cultural product whose doctrines and practices evolved over time in response to changes within Judaism and through interaction with non-Jewish cultures.

The word “kabbalah” means “reception” and in the context of rabbinic Judaism the term refers to the reception of divine instruction, namely, revealed knowledge. According to rabbinic Judaism, God revealed to the People of Israel a dual Torah: a written Torah and an Oral Torah. Medieval kabbalists saw themselves as recipients of Oral Torah par excellence, since kabbalah for them constituted the inner, esoteric meaning of the revealed Written Torah. As such, kabbalah pertained to the mysteries of God, the universe, and the Torah that exceed the ken of ordinary human apprehension and cognition. These secrets had to be disclosed only to the initiate few who were spiritually prepared to receive the privileged information and deserved the benefit from it. Ordinary Jews, let alone non-Jews, were not to have access to this restricted information lest they be led to insanity, reach mistaken conclusion about God (i.e., idolatry), or even risk death. To ensure that esoteric content would be transmitted only to those who deserve it, kabbalah was originally transmitted orally from authorized teachers to worthy disciples within the confines of rabbinic academies and specific kinship groups.

The intellectual roots of kabbalah can be traced to rabbinic esoterica of late antiquity, one strand of which depicted heavenly ascents in which the mystic envisions the beauty of God seated on a throne. These ecstatic experiences were believed to be dangerous and could be endured only because the mystic was protected by magical formulas that contained the power of the Divine Name. The depiction of God's luminous, noncorporeal form in a literary tradition known as *Shiur Qomah* (Measurement of the [Divine] Stature) became most problematic in the eighth century when rabbinic esoterica was edited in the Islamic East. Islamic rationalism, interreligious debates, and Karaite sectarianism brought about a critique of rabbinic esoterica, especially the blatant anthropomorphism of some rabbinic midrashim and the speculations about God's luminous body. To survive the critique, rabbinic Judaism had to be given a rationalist, systematic interpretation with the help of contemporary science and philosophy.

Kabbalah in the Middle Ages

The articulation of Jewish philosophy functioned as a catalyst for the emergence of kabbalah. The process began with speculation about a short and enigmatic book, *Sefer Yetzirah* (Book of Creation), whose earliest variants were probably composed in the Hellenistic period. The text was edited in the Islamic East during the ninth century when Islamic intellectuals, the *Ikhwan al Safa*, articulated a philosophy of nature based on number symbolism and linguistic ontology. Attributed to the patriarch Abraham, *Sefer Yetzirah* speaks about the creation of the world by God by means of 32 paths of wisdom: 10 *Sefirot* and 22 letters of the Hebrew alphabet. The *Sefirot* are understood either as ideal numbers or as powers that govern the creation of the physical cosmos, clearly reminiscent of the Neo-Pythagorean conception of numbers. The Jewish intellectuals who generated *Sefer Yetzirah* regarded creation as a linguistic process and the cosmos was a linguistic construct made out of infinite permutations of the letters of the Hebrew alphabet, each

of which has a numerical value. From the tenth to the twelfth centuries Jewish thinkers in the Islamic East, North Africa, Italy, and Spain composed commentaries on *Sefer Yetzirah* in which they debated the meaning of the *Sefirot*, a theoretical debate that pertained to the ontological status of divine attributes.

These commentaries were known to a group of Pietists in Germany (*Hasidei Ashkenaz*) who preserved rabbinic esoterica and developed a distinctive spiritual culture. The group generated *Sefer Hasidism* (The Book of the Pietists), under the leadership of Judah ha-Hasid (d. 1217). This anthology of ethical instructions, folktales, anecdotes, demonology, and magic constituted the exoteric teachings of the group shared with the Jewish community at large. For their own consumption, the German Pietists speculated on the Hebrew language as the grammar of reality, and especially about the divine Glory (*kavod*), the incorporeal addressee of prayers. They visualized the Glory and developed a sexualized, symbolic language to refer to the realm of the divine chariot (*merkabah*) upon which the divine Glory was seated. The feminine quality of the Glory was identified with the Shekhinah and was imaged in multiple ways (e.g., crown, prayer, the divine voice, the king's daughter, or bride). The destruction of the Rhine Valley communities in the First Crusade (1096) stimulated the writing down of these esoteric traditions, which would influence the emergence of medieval kabbalah.

A different, philosophical spirituality was cultivated among the Jewish courtier class in Muslim Spain during the eleventh and twelfth centuries, which developed a blend of Neoplatonic and Hermetic views, culled from Muslim texts and adapted to Judaism. In the second half of the twelfth century, however, this blend was supplanted by Aristotelianism as the dominant philosophical schema for Jewish intellectuals in Spain, although it too was suffused with Neoplatonic themes. The leading figure in this development was Moses Maimonides (d. 1204) and his interpretation of rabbinic Judaism would eventually become normative. Maimonides' intellectualist reinterpretation of rabbinic Judaism was yet another impetus for the emergence of medieval

kabbalah. In critique of Maimonides' view, a group of scholars in Provence who called themselves "masters of kabbalah" articulated an alternative interpretation of Judaism. In the beginning of the thirteenth century, the first kabbalistic commentary on *Sefer Yetzirah* was composed by Rabbi Isaac Sagi Nahor ("The Blind") (d. 1235) who began to articulate kabbalistic symbolism. It emphasized the immanence of God contrary to the remote and uninvolved God of the rationalist philosophers. The process by which the concealed God has revealed Himself was now systematized in writing and could be studied by others.

It is very likely that the early kabbalists in Provence were also responsible for the editing and circulation of yet another foundational text in the history of kabbalah – *Sefer ha-Bahir* (Book of Brightness). This text too is pseudo-epigraphic, attributing its views to the second-century rabbi, Nehunya ben ha-Qanah, the hero of ancient rabbinic esoterica. Written in Hebrew with occasional Aramaic phrases, the *Bahir* uses the literary form of parable (*mashal*) to teach deep truths about an earthly king, his royal family, his loyal and disloyal subjects, and his majestic palace. The language is often symbolic; some of the symbols are taken for granted without further exposition, while others lead to an extended narrative. In the *Bahir*, speculations about the ten divine potencies, the *Sefirot*, express a mythical conception of God because the *Sefirot* are viewed as character traits of the divine personality. Unlike the philosophers who viewed God as an intellect that thinks itself, the people who studied the *Bahir* delved into the inner life of God's personality, perhaps reflecting the so-called "rise of the individual" that medievalists associate with the Renaissance of the twelfth century. The symbolism of *Sefer ha-Bahir* would later be elaborated by the kabbalists during the thirteenth century, active mainly in Spain.

In the first decades of the thirteenth century, kabbalistic speculations, now available in writing (despite the commitment to esotericism), began to disseminate in the Jewish communities in Catalonia. In the town of Girona a small coterie of Jewish intellectuals who were at home with

Neoplatonic philosophy – R. Ezra ben Shlomo, R. Azriel, R. Jacob Ben Sheshet, and R. Moses ben Nahman (Nahmanides) – developed the teachings of Provencal masters further through commentaries on Talmudic homilies, the Song of Songs, *Sefer Yetzirah*, the Hebrew alphabet, and Genesis. From this perspective, their kabbalistic discourse was decidedly traditional. The fact that Nahmanides (d. 1272), the leader of Catalanian Jewry, was associated with the group gave authority to kabbalah as an alternative to Maimonidean rationalism. Nahmanides, however, was deeply committed to esotericism and restricted the dissemination of kabbalah to the initiated few, forbidding the employment of creative imagination in Scriptural interpretation.

During the early 1230s, Jewish communities of Spain and Provence debated the validity of Maimonides' legacy, focusing on the proper approach to the biblical text, especially the creation narrative of Genesis. Those advocating Maimonides' approach understood the biblical text in accord with Aristotle's physics and cosmology, whereas the kabbalists claimed that the creation narrative pertains to processes within God. At stake were not only the exegesis of Scripture but also the nature and observance of the commandments. Maimonides' historicized interpretation of the commandments rendered them as a means to an end, whereas the theosophic kabbalists offered a sacramental view of Jewish rituals: each commandment is linked to an aspect of God so that performing a given commandment with the proper intention empowers God. Despite these differences, philosophers and kabbalists had much in common: both groups were elitist and believed that their privileged knowledge should be known by the few; both claimed to possess knowledge of ultimate truth which they regarded as salvific; both assumed the biblical text to be esoteric and offered their way to decode the text; both were open to non-Jewish strands of thought although the rationalist philosophers were Aristotelian, whereas the kabbalists perpetuated Neoplatonic, Ismaili, and Sufi paradigms.

In the second half of the thirteenth century, rationalist philosophers relaxed their elitism that

had characterized the teachings of Maimonides and began to popularize philosophy through translations of Averroes' commentaries on Aristotle into Hebrew, commentaries on Maimonides' *Guide of the Perplexed*, philosophical encyclopedias, and philosophical novels. The philosophically informed interpretation of Judaism could thus become official Jewish theology for Spanish Jewry. That prospect compelled kabbalists to take a public stand and to present their alternative to rationalist philosophy. Between 1270 and 1290 kabbalists left behind the restrictions articulated by Nahmanides and committed their creative insights to writing. Kabbalah now received its "classical" formulation in *Sefer ha-Zohar*, the most creative composition of Sephardic Jewry.

The *Zohar* presents itself as a commentary on the Torah articulated by the second-century Rabbi Shimon bar Yohai in his conversations with his companions while they were strolling through the Holy Land. The *Zohar* was composed in the last quarter of the thirteenth century in Castile, probably by a mystical fraternity, at the center of which was Moses de Leon (d. 1305). The *Zohar* was written in Aramaic in order to give it the appearance of an ancient Midrash, but it is full of neologisms and words that betray its medieval context. The homilies of the *Zohar* focus on the unique personality of its protagonist, Rabbi Shimon bar Yohai, who is portrayed as a righteous person endowed with supernatural powers, a perfect mystic, master teacher, and a shaman who is able to impact the supernal world of the *Sefirot* as well as transform the physical world through miracles. The primary activity of the Zoharic group is Torah study, a redemptive activity that is depicted in highly sexual overtones. The mystics of the *Zohar* love God and love Torah and the erotic nature of their constant study of Torah is expressed through the love poetry of the Song of Song, the text most associated with the ancient text of *Shiur Qomah*. The major focus of the Zoharic group is the feminine aspect of God, the Shekhinah, whose precarious existence is threatened by the powers of evil, ruled by the archdemon, Samael. The mystical goal of the Zoharic group is to identify

with the Shekhinah, surrender themselves to her, and ultimately unite with her.

The *Zohar*'s artistry, rich symbolism, and eroticism made it an irresistible literary text, worthy of imitation, translation, and commentary. In the fourteenth century, kabbalists imitated the style of the *Zohar*, composed dictionaries to its Aramaic language, generated lists of kabbalistic symbols to decode the *Zohar*, and began to write commentaries on the *Zohar*. In the late Middle Ages, Jews took the *Zohar* to be an authentic ancient Midrash, and that assumption contributed to the positive reception of the *Zohar* in the premodern period. Yet, as much as the dissemination of kabbalah in the early modern period was tied to the reception of the *Zohar*, the historical critique of kabbalah in the modern period involved a challenge to the *Zohar*'s claim for antiquity.

With the consolidation of theosophic kabbalah in the *Zohar*, the difference between rationalist philosophy and kabbalah became evident also in regard to attitudes toward the natural world. Whereas the rationalist philosophers sought to understand the laws of nature by virtue of the physical sciences as defined by the Aristotelian traditions, the kabbalists regarded nature as a text that mirrored God. Nature was believed to be constructed of the Hebrew letters (an idea traced back to *Sefer Yetzirah*), the basic units of information whose endless combinations mysteriously give rise to physical reality and all forms of life. The textualization of nature made kabbalistic discourse rich in organic symbolism, but it did not make the kabbalists interested in the study of the natural, corporeal world for its own sake. It was precisely the physical reality of natural things that the kabbalists claimed to transcend and decode by means of their hermeneutical procedures. The sacred life of the kabbalists did not revolve around the study of nature but around the endless interpretations of the sacred text and the infinite permutations of the Divine Name. This hermeneutical activity was enhanced by the *Zohar*, which presented itself as the revelation of the cipher required to decode the Torah. Based on the linguistic mysticism prevalent in thirteenth century kabbalah in Castile, the *Zohar*

provided the grammar of reality, so to speak. When the *Zohar* itself became the focus of study, commentaries on the *Zohar* further enhanced the primacy of textuality in kabbalah, rendering kabbalah even less interested in observation of nature. Kabbalah thus retarded Jewish interest in the study of nature, the goal of scientific inquiry.

In the mid-sixteenth century the *Zohar* became a canonic text, second in importance only to the Talmud. This development was aided by the expulsion of the Jews from Spain in 1492, the growing interest in kabbalah among Christian humanists, the attacks of the Papacy on the Talmud and the burning of the Talmud in 1553, and the printing of the *Zohar* in 1558–1559 in Italy, an event accompanied with heated controversy.

In Italy, the *Zohar* replaced the intellectualist kabbalah of Abraham Abulafia (d. ca. 1292), a close reader of Maimonides' *Guide of the Perplexed* who believed to have achieved the cognitive ideals of Maimonidean philosophy – the mystical union of the human intellect with the Active Intellect. Abulafia's the so-called "prophetic kabbalah" or "ecstatic kabbalah" creatively blended ancient Jewish esotericism, German Pietism, theosophic kabbalah, and Maimonides' rationalist philosophy. Abulafia identified the *Sefirot* with the Separate Intellects, but gave this idea an anthropological or psychological interpretation: the *Sefirot* are internal states of human experience; they are part of the human psyche, since the human is a microcosm of the macrocosm. Knowledge of the *Sefirot* is a form of self-knowledge, a process that requires the acquisition of moral and intellectual virtues and that culminates in the conjunction between the human intellect and the Active Intellect. This cognitive union is prophecy, a reception of divine efflux from God through the Active Intellect, precisely as Maimonides explained. The kabbalah of the *Sefirot*, anthropologically or psychologically interpreted, is thus the highest example of the philosophic maxim "Know Thyself."

The main obstacle to self-knowledge is the corporeal body itself, especially the power of imagination. However, the Jewish tradition itself,

according to Abulafia, also reveals the way to break through human embodiment and to free oneself from the errors of human imagination. This is the highest form of kabbalah, "the path of the [divine] names" (*derekh ha-shemot*), which is religiously superior to the knowledge of the *Sefirot*. Building on the linguistic theory of *Sefer Yetzirah* and the mystical practices of the German Pietists, Abulafia articulated exegetical, meditative, and contemplative techniques that supposedly resulted in a mystical union with God. However, like the theosophic kabbalists, Abulafia rooted the mystical path in the Hebrew language itself, which he regarded as the "mother of all languages" because it is "in accord with nature." God chose Hebrew to be the language for the creation of the universe because of the unique perfect properties of Hebrew.

Abulafia's kabbalah was a full-fledged, experiential program to achieve paranormal psychic states that culminate in a mystical union with the Active Intellect. As a result, the human intellect attains immortality, precisely as Maimonides taught. In addition to the performance of the commandments and rigorous learning of philosophy and its sciences, Abulafia's program included seclusion, breathing techniques, physical postures, recitation of divine names, visualization of letters and letter combination. Most of these techniques were developed on the basis of existing Jewish practices, but some have analogs in other mystical systems, mainly Sufism, and were influenced by the contact Abulafia had with Sufis during his travels in Palestine and the Balkans and through the writings of ibn Arabi which he encountered in Spain.

Kabbalah in the Early Modern Period

Abulafia's works and other kabbalistic texts were translated into Latin by Flavius Mithridates (d. 1483). Mithridates elaborated these translations with his own forgeries. Kabbalah then became of great interest to Christian humanists such as Pico della Mirandola (d. 1494), Pico's nephew, Alberto Pio (d. 1530), and Yohannes Reuchlin (d. 1522) who regarded kabbalah as part

of *prisca theologia*, which culminated in the truths of Christianity. In 1558–59, 5 years after the Talmud was publically burned as a blasphemous text, Christian humanists sponsored the printing of the *Zohar* in two printing presses, one in Mantua and the other in Cremona, and kabbalah was presented as the inner truth of Christianity. It was believed that the dissemination of kabbalah among Christians would encourage Jews to convert to Christianity.

Christian kabbalah developed as a distinctive interpretation of Christianity, inseparable from the contemporary fascination with the occult properties of language. For Yohannes Reuchlin and his followers, for example, Hebrew was a pure, natural language, the foundational structure of the created universe. Knowledge of Hebrew along with the unique vocalization, punctuation, and accents was therefore conducive to knowledge of nature as much as it was conducive to the salvation of the individual soul. If the *Zohar* indeed contained spiritual truths whose revelation could bring about the redemption of the Jewish people, publishing the *Zohar* was a religious obligation of the highest order. Jews who supported the printing of the *Zohar* collaborated with the Christian publishers and helped in the translations of the *Zohar* into Latin.

In 1555, Jews residing in the Papal States were forced to live in ghettos by decree of Pope Paul IV. In the Italian ghettos, kabbalah would be studied by voluntary associations, or confraternities, who found solace in the spiritual message of the *Zohar* and its symbolic understanding of reality. However, whereas in sixteenth-century Italy the *Zohar* was perceived as part of ancient philosophic lore, in North Africa the *Zohar* was regarded as a holy book that had to be treated as a sacred object because it contains occult powers that bring concrete benefits to those who study it. In the Draa Valley of Southern Morocco, kabbalah was cultivated under the influence of local Sufi practices, such as ritualized recitation of divine names and communication with the souls of deceased saints.

In Safed, a small town in the Upper Galilee of the Land of Israel, a mystical fellowship made up mainly of refugees from the Iberian expulsions

brought about the next main development of kabbalah. Under the leadership of Moses Cordovero (d. 1570) and then Isaac Luria (d. 1572), this kabbalistic fraternity lived an intense religious life in expectation of the imminent coming of the messiah. Obsessed with personal guilt and the catastrophic nature of Israel's exile, the kabbalists of Safed devised an elaborate spiritual program that included ascetic practices and penances for sins in order to cultivate spiritual virtues such as modesty and humility. The intense introspection and self-examination was designed to purify the soul and facilitate communion with God. Additionally, this goal required specific mystical practices such as social isolation and seclusion, reduction of verbal communication to the minimum, meditation and recitation of divine names, and withdrawal from contact with material objects so as to minimize bodily sensations. Other practices included prostration on the grave sites of ancient rabbis to commune with their departed saintly souls (*yihuddim*) and outdoor peregrinations to encounter the Shekhinah (*gerushim*). The kabbalists of Safed, like the literary figures of the *Zohar*, identified themselves with the suffering of the Shekhinah and acted to rescue the feminine aspect of God from its suffering. All of these mystical techniques and practices yielded visual and auditory revelatory experiences which were given normative power not only because they were associated with the figure of Elijah, but because some of the mystics, especially Joseph Karo (d. 1575), were regarded as authoritative interpreters of Jewish law.

Underlying the mystical practices of the Safed community was an elaborate cosmogonic myth about events that took place within the Deity: the "withdrawal" of God into Himself (*tzimtzum*), the expansion (*hitpashtut*) of Divine Light into the structure of Divine Anthropos (*Adam Qadmon*), the catastrophic breakdown of the divine "vessels" (*shevirat ha-kelim*), and the redemptive repair of the broken deity (*tiqqun*). These processes, which Isaac Luria and his disciples described in great detail and specificity, were to account for the disharmonious condition of the universe, the human, and the People of Israel. The elaborate theogonic and cosmogonic

myth was the theoretical rationale for the mystical practices of these religious virtuosi. It was held that the kabbalist, whose own soul is healed by living the mystical way, was able to repair the broken universe and the broken deity. In the mending or healing of the world and of God lies the messianic import of Lurianic kabbalah. Isaac Luria understood himself in messianic terms but did not declare himself publicly as a messiah. His students – Hayyim Vital (d.1632), Joseph ibn Tabbul (d. ca. 1590), and Israel Sarug (d. 1610) – would offer divergent interpretations of the Lurianic narrative which they took to be the science of divinity.

Lurianic kabbalah spread in the seventeenth century to Italy, Central Europe, and Amsterdam, especially among former conversos. For Abraham Cohen Herrera (d. 1635), for example, the elaborate myths of Lurianic kabbalah were totally compatible with renaissance Platonism, even though kabbalah was not reducible to Platonism. Exposed to Lurianic kabbalah through the teachings of Israel Sarug, Herrera diminished the messianic orientation of Luria as he interpreted the stark anthropomorphism of Lurianic kabbalah philosophically. Herrera's interpretation of kabbalah was known to Benedict Spinoza (d. 1677), and probably had some influence on the latter's philosophic monism, in which there is only one substance: God/Nature. Other ex-converso scholars in seventeenth century Amsterdam who promoted kabbalah included Menasseh ben Israel (d. 1657), the advocate of Jewish resettlement in England who had personal contact with leading Christian scholars of the time, members of the "Republic of Letters." Menasseh ben Israel showed the affinity between kabbalah and Platonism, and went on to discuss the letters of the Hebrew alphabet as the "lights of the Sefirot." For ben Israel, the letters function like the Platonic Ideas, a notion already stated in the late fifteenth century by several Jewish philosophers.

In the mid-seventeenth century, Jews and non-Jews in Amsterdam and England were influenced by the Jewish messianic movement associated with Sabbatai Zevi (d. 1675). Born in Smyrna, Zevi declared himself to be the messiah in 1648

after devoting himself to the study of the *Zohar* and kabbalistic texts composed in the Byzantine Empire. He was expelled from Smyrna by the unsympathetic rabbinic leadership, but found his way to Salonika, Istanbul, Jerusalem, and Cairo, places where he engaged in non-normative acts, in which he either defied rabbinic authority or negated accepted Jewish practice. In May 1665, Zevi declared himself once again a messiah, but this time in Jerusalem, the place from where the messiah was indeed to appear according to the Jewish tradition. Now, his messianic claims were taken seriously by Nathan of Gaza (d. 1680), a Lurianic kabbalist and spiritual healer, who became Zevi's propagandist. Nathan of Gaza would cast the idiosyncratic behavior of Zevi, including his later conversion to Islam (1666), in the garb of Lurianic theology, although it was quite different from the initial teachings of Luria. In contrast to the Lurianic orientation of Nathan of Gaza, Zevi's personal faith was shaped by his own mystical experiences and his peculiar psychological makeup.

The Sabbatean movement lasted throughout the seventeenth century and well into the eighteenth century. It was condemned by rabbinic authorities as a heresy and was driven into clandestine existence. Sabbatean cells in Turkey, Italy, Germany, and Poland persisted despite the persecution and eventually gave rise to the heretical sect of Jacob Frank (d. 1791) in Poland. He considered himself an incarnation of Zevi's soul, and in imitation of Zevi, he also converted, in his case, to Christianity. Frank's theology was a blend of kabbalah, Christianity, and some modernist views all practiced with the intent of liberating his followers (who likewise converted to Catholicism) from the shackles of Judaism.

While the Frankists expressed their heretic views, a spiritual revival movement would reshape the life of Jews in Eastern Europe in the second half of the eighteenth century – Hasidism. The movement is associated with Israel Baal Shem Tov (d. 1760), a folk healer, magician, and exorcist, regarded as the founder of Hasidism. His interpretation of kabbalah focused on prayer as an exuberant experience filled with joy in which negative thoughts are transformed into

positive awareness of God. The charismatic leadership of the founder was eventually replaced by a more structured organization and Hasidism developed its own theology on the basis of Lurianic kabbalah. Hasidic masters, however, communicated their teaching in stories, parables, and oral exposition of the weekly Torah portions that wove kabbalistic doctrines (especially of Lurianic kabbalah) into a highly creative interpretation of the received rabbinic tradition. Hasidic stories and sermons (delivered in Yiddish but often written down in Hebrew) expanded the appeal of Hasidism and made exuberant experiences accessible to the many. The literary style and the psychological interpretation of kabbalah account for much of the mass appeal of Hasidism. Hasidic teachings minimized the mechanistic and catastrophic aspects of Lurianic theology, and instead interpreted the major events of God's evolution as states of consciousness. The psychological emphasis shifts the messianic drama from the public arena to the private sphere, and to the redemption of the individual Self.

As successful as the Hasidic movement was, it also generated fierce opposition. The traditional opponents (*mitnagedim*) of Hasidism claimed that it paid too little attention to Torah study, and diminished the importance of intellect in the pursuit of religious perfection; that it introduced a highly emotional and undignified style of worship; and that it was rife with non-Jewish folk traditions. While these opponents considered Hasidism an affront to traditional Jewish learning and leadership, the proponents of the Jewish Enlightenment (the *maskilim*) scorned Hasidism for its superstitious, and unenlightened views.

Kabbalah in the Modern Period

While the proponents of Hasidism and their opponents in Eastern Europe battled over the correct interpretation of Judaism, Jews in Central and Western Europe struggled to be granted civil rights as citizens of a modern state. The Jewish demand for emancipation was rooted in the awareness that Judaism is culturally backward and that if Jews are to be integrated into European

society, Jewish religious practices must be thoroughly transformed. Those who agitated for the reform and modernization of Judaism adopted the logic of historical inquiry about the Jewish past and promoted the Science of Judaism (*Wissenschaft des Judentums*). Looking at Judaism in a disinterested fashion, the scientific study of Judaism was to discover the truths about the Jewish past and separate that which is essential to Judaism (e.g., monotheism) from that which is a product of historical circumstances (e.g., the rituals of Judaism). In the pursuit of objective truth about the past, all claims were to be examined critically with the help of philology and the commitment to the recovery of the past as it truly was. The historical analysis of the past was to be applied first and foremost to the immediate medieval past including philosophical and kabbalistic strains of medieval Judaism.

The Jewish historians of the nineteenth century were largely unsympathetic to kabbalah. The symbolic worldview of kabbalah, its valorization of the imagination, and its association with magic and astrology were all taken to be manifestations of a superstitious worldview that was not only antithetical to modern rationalism, but also the cause for the continued backwardness of the Jews. The integration of Jews into Western society and culture demanded relinquishing the commitment to kabbalah, speculative or practical. The historical approach to the Jewish mystical tradition, however, also contributed to the spread of kabbalah because it brought kabbalistic sources to a wider audience. Such sources included critical editions of seminal texts, monographs on outstanding authors, and initial interpretations of the historical development of the Jewish mystical tradition.

Gershom Scholem (d. 1982) dominated the modern study of kabbalah in the twentieth century. Contrary to his predecessors in Germany, Scholem saw in the academic study of the Jewish mystical tradition a lever to promote the Zionist critique of Jewish integration into Western culture. Soon after he migrated to Palestine in 1923, Scholem was among the founders of the Hebrew University in 1925, where the study of kabbalah was to be conducted with utmost commitment to

scientific method. Under Scholem, the academic study of kabbalah was professionalized and kabbalah was incorporated into the study of religion in academic settings. The focus was textual and philological, and Scholem deliberately ignored the actual practice of kabbalah in Palestine, North-America, or Europe and dismissed attempts to integrate kabbalah and modernism.

The most influential of modernist kabbalists in the twentieth century was Yehudah Leib Ashlag (d. 1954), who was exposed to kabbalah through Hasidism. Ashlag settled in Palestine in 1921 and devoted his life to the dissemination of egalitarian and highly psychological interpretations of Lurianic kabbalah. He translated the *Zohar* into Hebrew with an extensive commentary, wrote commentaries on Lurianic kabbalah, and composed political tracts for the general public. The ideal society, so Ashlag believed, is a Communist community in which one works according to one's ability but receives according to one's needs. In the second half of the twentieth century, students of Rav Ashlag (e.g., Rabbi Philip Berg, and his sons, Michael Berg and Judah Berg, as well as another popularizer of kabbalah, Michael Laitman) are engaged in the dissemination of Ashlagian kabbalah in Israel and all over the world through special learning centers (e.g., The Kabbalah Center) and through the Internet. The attraction of several Hollywood celebrities (most notable being Madonna) to kabbalah has further increased its popularity in the USA. Marketed as "a technology of self-transformation," kabbalah appeals to baby-boomers who seek meaning and personal happiness.

In the USA and in Israel, kabbalah has become exceedingly popular in print, public happenings, performances of spiritual poetry and music, adult education courses, radio broadcasts, columns in daily newspapers, and Internet blogs. Kabbalistic language, symbolism, and outlook are ubiquitous and kabbalah is studied on all levels whether or not one lives a traditional Jewish life and whether or not one is intellectually and spiritually competent to study kabbalah.

In North America, kabbalah is disseminated primarily through the mediation of Hasidism. Interest in kabbalah began to take root during

the counterculture revolution of the 1960s when young American Jews found the style of American suburban synagogues unappealing and sought new spiritual self-expression. Under the influence of Abraham Joshua Heschel (d. 1972), a scion of a famous Hasidic family, these spiritual seekers found their way to Hasidic and kabbalistic texts; some studied them academically and others began to search for a Neo-Hasidic interpretation of kabbalah fit for the sensibilities of a New Age. At the helm of the Jewish Renewal Movement was Rabbi Zalman Schachter-Shalomi (b. 1924), an original, creative mystic who encouraged the incorporation of kabbalistic symbolic terminology and the psychological interpretation of kabbalah. The movement continues to influence the spiritual life of American Jews, although it remains small in number.

Today, kabbalah has become a popular phenomenon in the USA, accessible to Jews and non-Jews alike, in part because of the outreach programs of one particular branch of Hasidism known as Chabad-Lubavitch. Founded by Shneur Zalman of Liadi (d. 1812), the grandson of the Baal Shem Tov, this brand of Hasidism was transported to the USA in the 1920s and was strengthened when Rabbi Joseph Isaac Schneerson (d. 1950) settled in New York in 1940 and began an aggressive outreach program to Jews. After the Holocaust, his son-in-law, Menachem Mendel Schneerson (d. 1994) intensified the outreach program through schools, youth camps, community centers, and "Chabad Houses" whose goal was to encourage Jews to lead an Orthodox Jewish life with the express intent of bringing about the messianic age. In these settings, Chabad emissaries introduce Jews to kabbalah as interpreted by the official teachings of the Chabad-Lubavitch movement, but with no interest in the history of kabbalah, let alone the relationship between kabbalah and non-Jewish culture.

Conclusion

Kabbalah is an important and creative body of teachings directed at fathoming the mysteries of God, the universe, and the Torah, which emerged

within rabbinic Judaism, evolved over time, and continues to shape Jewish life. Kabbalah also exerted a deep influence on Christianity through what became known as the Christian kabbalah. The esotericism that characterized the early kabbalistic teachings was breached by the mid-sixteenth century when its major canonic text was printed. Kabbalah enhanced and deepened Jewish religious life over the centuries, but it also gave rise to heresies such as Sabbateanism and Frankism. The relationship of kabbalah and science is complex and even contradictory. On the one hand, the excessive focus on textuality in kabbalah made its adherents uninterested in the study of the physical world, but on the other hand, the notion that the world was essentially a linguistic construct encouraged some kabbalists, especially during the Renaissance, to engage in alchemy, astrology, astral medicine, and talismanic magic because they claimed to know the basic grammar of reality. Today, kabbalah is attractive to many scientists, especially those interested in mathematics or information science, and psychology. In the beginning of the twenty-first century, kabbalah informs many aspects of contemporary Judaism in the Diaspora and in Israel and has infiltrated all aspects of popular culture.

Kamma (Pāli)

- [Karma \(Buddhist\)](#)

Kamma/Karma

Ven. Agganyani

German Vinaya Sangha Association (DBO) and
Centre for Buddhist Studies (CBS), Myanmar,
Bruckmuehl, Germany

Kamma (Sanskrit: *Karma*), which literally means “action,” is used by the Buddha only as “intentional action,” it might be a physical, verbal, or mental action. “It is motivation (*cetanā*), o monks, what I call kamma.” (“*Cetanā’ham, bhikkhave, kammaṃ vadāmi*”, Collection of Gradual Discourses, Aṅguttara-Nikāya, A VI. 63)

The mental factor (*cetasika*) *cetanā* is motivation, stimulation, intention, or volition. Only *cetanā* associated with unwholesome or wholesome types of consciousness is *kamma*.

While one performs intentional actions, a kammic energy is produced laying latent as a potential which can bring about its kammic result or fruit, called “*vipāka*,” later.

There are various types of kamma concerning its function, the priority of its ripening, the time of maturity, and the plane where it can produce its result. According to function, one of them is producing *kamma*, which produces a new life. Others can support, obstruct, or destruct this *kamma*. *Kamma* is often compared with a seed which has the potential to produce only a species of the same kind but only with present suitable conditions like water, Earth, Sun, etc. *Kamma* alone also cannot bear its effect, but it is the main cause of the kammic result. Results of kamma can be mental and physical.

Abhidhamma shows clearly that not all is *kamma*, and not all is *vipāka*, one’s fate. One performs new *kamma* during the impulsion stages (*javana*) of a mental process (*vīthi*) only (The mental process and its various stages as well as *kamma* are explained in Abhidhammattha Sangaha and its commentaries. See, e.g., Process of Consciousness and Matter, by Dr. Rewata Dhamma, Burmingham Buddhist Vihara, 2007 (<http://www.bbv.org>).

uk/), Triple Gem Publications. Free download: http://www.abhidhamma.com/Process_of_consciousness_and_matter.pdf). Other stages, like eye consciousness, are its resultant (*vipāka*). Not everything is determined – there is no fatalism, although our “free will” is limited.

Kamma (Pāli)

Description

The word karma means simply “action,” although in modern parlance it is generally used as a shorthand for *karma-vipāka*, the result of intentional action. In the ancient Indian setting, the Buddhist position on karma appears to have taken a middle path position between two standpoints. One of these two is karmic determinism, according to which the results of each and every action would have to be fully experienced. Hence, the path to liberation in traditions adopting this standpoint requires expiating the results of former deeds. The other standpoint appears to have denied the existence of karmic results and advocated that deeds have no consequences at all. Both are considered by the Buddhist tradition as mistaken views on the nature of karma.

From a Buddhist perspective, the key factor in the performance of a deed is one’s own mental volition (Morris and Hardy 1885–1900, III 415), since volition is what leads one to speak or physically act in a particular way. This invests the ethical quality of one’s own volition with crucial importance; hence, the dominant concern in early Buddhist thought is with mental culture and ways of training the mind.

The Buddhist conception of karma holds that one's deeds will inevitably have results. A stanza poetically proclaims that neither up in the sky nor deep down in the ocean will it be possible to escape the retribution for one's evil deeds (Hinüber and Norman 1994, Stanza 127). However, the form that such retribution takes is said to depend on the overall situation of the person in question. The same unwholesome deed will thus have a considerably stronger effect when it is performed by someone who habitually does evil, in contrast to someone who generally lives a wholesome life. This difference finds illustration in a simile of a lump of salt that is thrown into a cup of water or else into a river (Morris and Hardy 1885–1900, I 250). While in the first case, the water becomes undrinkable, in the case of being thrown into a river, the lump of salt hardly has any effect on the drinkability of the water.

Karma is, however, not the sole determinant of one's experiences, which besides being the results of former deeds are also the outcome of a variety of other factors (Feer 1884–1898, IV 230).

Another aspect of karmic retribution is that its effect may manifest in the present life as well as in future lives. This provides the background for appreciating the case of a serial killer by the name of Aṅgulimāla, who converted to Buddhism, became a monk and eventually reached full awakening (Trenckner and Chalmers 1888–1896, II 103). The fact that, in spite of his former criminal activities, he was able to reach complete awakening and become an arahant illustrates that, from an early Buddhist perspective, the gaining of awakening does not depend on expiating all the results of one's former deeds. Had a full experiencing of the fruits of his murderous activities been required, he would hardly have been able to progress to full awakening within a single lifetime. By becoming an arahant, Aṅgulimāla had gone beyond future rebirth and thus was able to avoid the retribution for his killing that would have awaited him in a future life, presumably to be spent in hell, had he not embarked on the path to awakening. All that he still had to experience was the retribution bound to ripen in his present life.

In order to fully appreciate the Buddhist teaching of karma, it needs to be considered in relation

to the not-self doctrine, which denies the existence of an eternal self (► [Anattā](#)). Instead of assuming an eternal and unchanging self at the core of subjective experience, Buddhism holds that the individual is made up of what are merely changing and conditioned processes. These processes continue during a particular lifetime and through subsequent rebirths. Thus, Buddhism does not reject the existence of an individual as a conditioned process – one of the central conditions operative in this process being precisely the results of karma – but only opposes the notion of an eternal substance or substratum.

From an early Buddhist position, the notion that the individual qua process is bound to change does not imply that it ceases and reappears every moment, as proposed during subsequent developments of Buddhist thought (► [Impermanence \(Buddhist\)](#)). Instead, the individual is simply seen as a changing process, perhaps best illustrated with the example of the steady flow of a river (Morris and Hardy 1885–1900, IV 137). Thus, future instances of the particular process that make up an individual will be the recipients of the karmic fruits of the actions done by the present and past instance of this particular individual process.

Unlike the basic principle underlying karmic fruition, the precise working out of karmic causes and effects are held by Buddhist tradition to be beyond the range of what can be ascertained by reflection, in the sense that it would not be possible to determine them with complete precision (Morris and Hardy 1885–1900, II 80). Presumably, too many causes and conditions are involved, making their interaction in a moment-by-moment changing situation something that cannot be predicted with exactitude. General patterns, however, can certainly be discerned. Thus, one discourse indicates that those who kill are in the future prone to be short lived themselves (Trenckner and Chalmers 1888–1896, III 203), just as harming others leads to being sickish oneself, anger results in ugliness, theft leads to becoming poor, etc. It is in this sense that, from a Buddhist perspective, living beings can be said to be the owners and heirs of their karma.

Key Stimulus

Jörg-Peter Ewert
Faculty of Natural Sciences, University of
Kassel, Schauenburg, Germany

The notion “key stimulus” belongs to a classical ethological concept. It refers to a stimulus (sign stimulus, releaser) that is adequate to activate an (innate) *releasing mechanism*. A key stimulus

represents a behaviorally meaningful object by a few characteristic features. The term “key” stimulus is based on the idea that the releasing features are analogous to a key which opens a lock. However, “key” may misleadingly suggest that the corresponding behavior were addressed just to *one* highly specific stimulus, so that the behavior failed to occur, if that unique stimulus were not available. Actually, no such case has been described. In fact, key stimulus comprises a category of objects. From this category, an object characterized by a certain feature configuration/combination has a maximal releasing value.

Knowledge, Sociology of

E. Doyle McCarthy
Department of Sociology and Anthropology,
Fordham University, Bronx, NY, USA

Description

Studies in the sociology of knowledge share a common theme, *the social foundations of thought*: ideas, concepts, and belief systems share an intrinsic sociality explained by the

contexts in which they emerge. From its origins in German sociology in the 1920s, the sociology of knowledge examines how ideas (knowledges) emerge out of and are determined by the social contexts and positions (structural locations) of their proponents. More recently, its subject matter has included not only a society's authoritative ideas and formal knowledges, but also those knowledges that operate in the realm of everyday life, informal knowledges.

According to its framers, Max Scheler and Karl Mannheim, *Wissenssoziologie* was an empirical and historical method for resolving the conflicts of ideologies in Weimar Germany that followed the political and social revolutions of the late nineteenth and early twentieth centuries, conflicts grounded in competing worldviews and directed by intellectual and political elites. The new discipline reflected the intellectual needs of this era, to bring both rationality and objectivity to bear on the problems of intellectual and ideological confusion. In this sense, classical sociology of knowledge has been described as a field of study that reflected a new way of understanding "knowledge" within a modern and ideologically pluralistic setting: The approach defines a new situation, summarily described as "modernity," a world where knowledge and truth have many faces (modern relativism). What we believe that we know varies with the cognitive operations of human minds and these vary by community, class, culture, nation, generation, and so forth.

For Max Scheler ([1924] 1980) who offered the first systematic outline of the discipline, the *forms* of mental acts, through which knowledge is gained, are always conditioned by the structure of society. While Scheler's original essays provoked commentary and debate, it was Karl Mannheim's formulation of the discipline in *Ideology and Utopia* ([1929] 1936) that defined the subject matter of the field for years to come; critics and contributors to the field defined their positions relative to Mannheim's arguments concerning ideology, utopia, and relationism.

Mannheim's treatise begins with a review and critique of Marxism and proceeds toward a theory

of the total conception of ideology: the mental structure in its totality as it appears in different currents of thought and across different social groups. Like ideologies, "utopias" arise out of particular social and political conditions but are distinguished by their opposition to the prevailing order. Utopias are the embodiment of "wish images" in collective actions that shatter and transform social worlds. Both concepts form part of Mannheim's broad design for a critical but nonevaluative treatment of ideology, one that supersedes the sociohistorical determinism and relativism of Marxism while moving toward a "relationist" notion of truth. From an analysis of the various and competing social positions of ideologists and utopians, a kind of "truth" emerges that is grounded in the conditions of intellectual objectivity and detachment from the social conditions that more directly determine ideas. *Ideology and Utopia* established the criteria for a valid knowledge, a *relational* knowledge, of sociohistorical processes. It raised the problems surrounding the historicity of thought and did this within the newly emerging academic discourse of sociology, thereby giving legitimacy to a new set of methodological issues involving the problems of objectivity and truth for the sciences and the humanities. Despite the many criticisms of *Ideology and Utopia*, the work received wide attention and appreciation inside and outside the social sciences where the problems posed by relativism continued to attract the attention of those working in the sciences and the humanities.

Werner Stark's *The Sociology of Knowledge* ([1958] 1991) prompted an advancement and redirection of the field, arguing for the embedding of sociology of knowledge within the larger field of cultural sociology. The sociology of knowledge is concerned with the "social determination of knowledge," not with the problem of ideology. Stark's book clarified the principal themes of writers who addressed the problem of the social element in thinking. He also intended it to serve as an introduction to the field that would prepare the way for a comprehensive history of the sociology of knowledge: theories of ideology of Marx and Mannheim; philosophical

speculations of the neo-Kantians Heinrich Rickert and Max Weber; views of the German phenomenological school of the 1920s, especially Scheler. Stark's strongest affinity was with Scheler's struggle to reconcile the antithetical claims of idealism and materialism, and his view of the sociology of knowledge as the foundation for a knowledge of "eternal values."

Contemporary sociology of knowledge addresses a related but different set of concerns than those posed by its founders, and its subject matter extends beyond the problems of relativism and the social location of ideas and ideologies. Among its themes are the "local" features of knowledges and the study of their functions in everyday life. This redirection of the field represents a shift from concerns with the truth-status of ideas and ideologies to the concerns of a cultural sociology of meaning, a movement away from a study of the ideological functions of elites and intellectuals to conceptions of knowledges as discursive (cultural) forms and as part of the entire range of symbolic and signifying systems operating in a society.

The most prominent contemporary argument in the sociology of knowledge was Berger and Luckmann's *The Social Construction of Reality* (1966). It advanced the position that sociology of knowledge is compatible with a view of sociology as a humanistic discipline and, the related argument, that "human reality" is a "socially constructed reality." The work moved the field further away from the study of theoretical knowledge or ideas and toward the (pre-theoretical) knowledge that social actors draw from in everyday life. Their treatise also redirected the traditional theory of social determination of ideas by social realities: social reality itself is a *construct*. The authors proposed that knowledge and social reality exist in a reciprocal or dialectical relationship of mutual constitution. This work placed the sociology of knowledge on a new footing whose focus was the broad range of signifying systems that form and communicate the realm of social realities. Since its introduction, the idea of a "constructed reality" has summarized a number of concerns of writers in the sciences and humanities that may

be described as the *problem of meaning* and the use of philosophical, literary, and historical approaches to study its social construction. Berger and Luckmann's treatise subsumed knowledges within a framework of interpretation, a ► [hermeneutics](#) that was decidedly cultural and semiotic, concerned with the symbolic and signifying operations of knowledges.

More recently, the "new sociology of knowledge" (Swidler and Arditi 1994; McCarthy 1996) can be seen as part of this larger movement in the social sciences, distinguished by a turn away from materialism and social structure toward semiotic and post-structural (Derrida, Foucault, Deleuze) theories that focus on the ways in which a society's meanings are communicated and reproduced. Swidler and Arditi (1994) also ask how social organizations (e.g., the media) order knowledges, rather than examining social locations and group interests. In light of new theories of social power and practice (Michel Foucault and Pierre Bourdieu), they also examine how knowledges maintain social hierarchies and how techniques of power are simultaneously and historically linked to knowledges. They join others in pointing out that newer theories of power, gender, and knowledge depart from the economic, class, and institutional focus of the classical sociology of knowledge.

Proponents of the new sociology of knowledge do not claim that the subfield has been entirely superseded by newer work in sociology and cultural studies. However, they note that the new sociology of knowledge is not a unified field, an argument also advanced by earlier writers who treated the sociology of knowledge as a "frame of reference" rather than a body of theory in its own right. In fact, this broad approach to knowledges as socially constituted – delineated in the early statements of Scheler, Mannheim, and other early writers in this field – today serves as a set of working propositions for a range of social scientists as well as for specialists in other disciplines, including the subfields of the history of ideas, social psychology, social studies of science, feminist theories, and cultural studies. In fact, a sociology-of-knowledge perspective – concerning group life and mind – has been

incorporated into the many subfields of sociology as well as sister disciplines from anthropology to history. Furthermore, as long as knowledges are understood as preeminently cultural phenomena, the more likely it is that the sociology of knowledge will be seen as a broadly inclusive set of theories and studies rather than a subfield with a distinct subject matter. Knowledges operate across the full extent of society, from the realm of everyday affairs to the institutions of law, politics, art, and religion, to the various sites and fields where knowledges are produced. The new sociology of knowledge examines the observable properties of knowledges in texts, modes of communication, and forms of speech within specific institutional settings.

The sociology of knowledge – much like the field of historical studies – reflects and advances further a distinctly modern set of presuppositions about human knowledge: *Knowledges develop out of particular sociohistorical circumstances and these circumstances inform what human beings know and their various ways of knowing.* Whatever one thinks about this relativistic set of presuppositions, a sociology-of-knowledge perspective has come to dominate the modern disciplines, certainly the social sciences but also the humanities, as well as other specialized fields like law and medicine. Put differently, modern ways of knowing – those of academics as well as all of us in the domain of everyday life – are characterized by the understanding that what people know and what they think are, in important ways, circumscribed by language and culture and that these develop and flourish in human communities of one kind or another.

These arguments have special relevance for both science and religion in the modern world. Among the many implications of a sociology-of-knowledge perspective for understanding these two knowledge domains, the most general and important one is that *all knowledges are situated*. Regardless of the truth claims of religion, for example, religious ideas, images, and symbols develop out of particular social worlds. Eternal religious verities take on a life within particular religious communities. Similarly, science itself – whatever final claims it makes

concerning a domain of reality (the human brain, sleep, or sex) – understands the relevance of history and sociology to its own enterprise. Increasingly today, practitioners of both science and religion draw from a sociology-of-knowledge perspective whenever they examine the changing and situated paradigms that make up their own disciplines. However else they understand their field of study today, they have come to recognize the legitimacy of grasping religion or science as a particular *discourse* or as a *social construction*, ideas first formulated by Scheler and Mannheim in the classic statements of Wissenssoziologie, almost a century ago. All knowledges, they argued, are cultural phenomena and this means that they are burdened with the presuppositions of their time and place, their *situation* (Wolff 1974).

Koch's Postulates

Li Yang Hsu

Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Robert Koch derived these postulates for determining microbial pathogenesis. These are as follows:

- The microorganism must be found in abundance in all organisms suffering from the disease.
- The microorganism must be isolated from a diseased organism and grown in pure culture.
- The cultured microorganism should cause disease when introduced into a healthy organism.
- The microorganism must be re-isolated from the inoculated, disease experimental host and identified as being identical to the original specific causative agent.

Landscape

Jesper Østergaard
Arts, Department of Culture and Society,
Aarhus University, Aarhus C, DK, Denmark

Related Terms

[Cosmology; Ritual; Temples](#)

Religions have persistent impact on the landscape they are situated in. The mutual integration of the cosmology and mythology of a religion with the geographical landscape alters believers' attitude towards both religion and landscape. The invisible, transempirical side of religion is supplemented by manifestations that make religion perceptually available for the believers. The visible, physical landscape manifests invisible aspects of religion, and thereby landscape supports religion as a shared and accepted part of human life. This mutual integration can take different forms (Hirsch and O'Hanlon 1995).

The landscape is organized by imposing meaning onto it through situating cosmology or mythological events in it, thereby establishing religious landmarks in the landscape that give

a cosmological order to it. Such places are often the location for rich ritual activity, sites of pilgrimage, or believed to be the location of a religious source of transformative power (Park 1994; Stump 2008).

Religious practices connected to these landmarks and other religious activities modify the landscape, either abruptly as when dolmens, temples, or other buildings are constructed or destroyed in order to build other ones or gradually as when pilgrimage routes slowly turn into proper roads, when religious institutions bring new crops or agricultural styles to a new area or the slow modification of rocks through the repeated touch by believers.

Landscape is demarcated according to religious maps, thereby enforcing certain restrictions and options for movements in the landscape. Temples, smaller areas, or sacred places may be off-limits to other than adherents of a certain religious tradition or only accessible for initiated religious specialists. Many of the conflicts between religious traditions in the world concern, among other issues, the conceptual and political control over territory (Bender 1993; Low and Lawrence-Zúñiga 2003).

The organization, modification, and demarcation of landscape are all parts of a process of the continuity of religions. Newborns inherit a world already constructed through religious practices, and as such the religious system presents itself as more natural than other religions. A foreign landscape may therefore be considered dangerous not only because the topological features like

mountains and rivers are different but also because they are imposed by other kinds of religious and cultural meaning. This landscape is unpredictable, since the religious and cultural system is unknown, and it is difficult to identify the demarcations and the landmarks. The religiously organized landscape also brings shared objectivity to the conceptual system of the given religion, since the landscape can be approached, perceived, and interpreted by groups of believers. The perception of the landscape is thereby informed by religious content.

Some religious traditions seek a very close connection between their cosmology, mythology, and rituals on the one side and the landscape on the other side, as when the gods are believed to live further up the mountain, below in the sea nearby, etc., or when rituals are performed in accordance with a calendar based on the sun's ascent or descent at a certain location in the horizon seen from a specific location. Such religious systems are necessarily local and small scale, and the religious conceptual system is likewise connected to the everyday life of the indigenous group. The religious conceptual system may provide locally relevant information, such as myths about the ancestors' ways of cultivating the land, rituals that seek to control the uncontrollable weather, or ideas that console in harsh conditions. Other religious systems de-emphasize the connection to landscape, striving instead for universal relevance of their belief system. The gods reside nowhere in particular and are best approached through construct places. These religions have better options for spread and distribution of ideas but may, as they spread, take on local forms in order to connect to new geographical landscapes.

Description

This discipline is devoted to the study of the French language and its literature from their origins to the present. Traditionally defined as a Romance language derived from Vulgar Latin

during the Middle Ages, French is spoken today by approximately 200 million people in over 50 countries around the world (Organisation internationale de la Francophonie 2007). Recent developments in this discipline reflect a shift in emphasis from the early periods and from France to the modern period and to French-speaking regions outside of France. For much of the twentieth century, the study of language was largely integrated with the study of literature. In recent decades, language study and linguistics have evolved away from literature, and literary studies have expanded to include Francophone studies, i.e., studies of texts written in French by authors from various French-speaking countries across the globe. Important subdisciplines within this field, as within other similar fields, include feminist and gender studies, film studies, cultural studies, critical theory, and foreign language pedagogy.

Self-Identification

Science

Within the field of French and Francophone studies, linguistics typically self-identifies as a science whereas literary studies are usually thought of as being opposed to science. According to French linguist André Martinet, “a study is said to be scientific when it is founded on the observation of facts and refrains from picking and choosing among the facts in the light of certain aesthetic or moral principles” (Martinet 1964). That literary studies are typically based on fictions rather than facts, and that the conclusions of literary scholars are often guided by aesthetic or moral principles are only two of the many reasons evoked in opposing literature to science, another of which being that, whereas science is said to destroy its past, literature conserves its history. Whereas new scientific discoveries make previous science obsolete, resulting in the removal of outdated books and journals from library shelves, literary works of the past are reprinted and studied as well as quoted by current authors.

Literary history nonetheless offers some notable exceptions to the commonly held notion of literature being incompatible with science. Literature of the French Renaissance includes several examples of “scientific poetry” which is said to stem from “a lyrical impulse both to praise and to caution against the awesome potentialities of human desire (*curiosité*) and thirst for knowledge (*science*),” and is referred to as displaying “an extraordinary variety of themes and styles, bringing together apparently unrelated ways of envisaging the universe: the scientific, the religious, and the magical, seen later as being at odds” (Wilson 1989). The effort to unite science and poetry is associated in the nineteenth century with the head of the Parnassian school, Charles Marie René Leconte de Lisle, who saw the poet as playing a “historical and scientific role in his attempt to rediscover for modern man the original sources from which all beauty and meaning proceed” (Denomé 1973). Renewed interest by scholars in the relation between science and literature during the final decades of the twentieth century is due, in part, to the influence of French philosopher Michel Serres whose work is characterized as running counter “to the prevalent notion of the two cultures – scientific and humanistic – between which no communication is possible. In Serres’s view ‘criticism is a generalized physics,’ and whether knowledge is written in philosophical, literary, or scientific language it nevertheless articulates a common set of problems that transcends academic disciplines and artificial boundaries” (Serres 1982).

Religion

Though not typically self-identified as a religion, French and Francophone studies can in many ways be thought of as bordering on religion. Leaving aside the broader question of language, the interpenetration of literature and religion can be ascertained from a variety of sources. The mixture of the sacred and the profane, which eighteenth-century critic Nicolas Lenglet-Dufresnoy associated with the earliest French literary compositions, is equally prevalent in works from later periods, as exemplified by

Gustave Flaubert's novel, *Madame Bovary*. French Romanticism is characterized by what Paul Bénichou has called the "consecration of the writer," citing Alphonse de Lamartine, Alfred de Vigny and Victor Hugo, who, beyond making religion a subject of their poetry, contributed to sanctifying the image of "the poet," whom they saw as accomplishing a sacred mission, and alternately referred to as a prophet, a teacher of peoples, and an interpreter of the divine word. The "consecration of the writer" in Romanticism from 1810 to 1830 is a manifestation of what Bénichou sees more broadly in the eighteenth and nineteenth centuries as the eclipsing of "the old religious system" by "a faith in which human beings, and not God, tended to occupy the primary position" (Bénichou 1999). From the 1830s forward, the rise of aesthetics in the face of what appears as a retreat of religion in modern democratic society can be traced in the writings of numerous authors, including Théophile Gautier and Charles Baudelaire, and is seen as culminating in Stéphane Mallarmé's conception of poetry as a substitute for religion, replete with its own mysteries and rituals.

While anxiety and religious faith remain a central concern for several prominent writers in the twentieth century, including Charles Péguy, Paul Claudel, and François Mauriac, the transfer of religion to the aesthetic domain is illustrated by Marcel Proust, who writes in a letter to one of his correspondents: "If I do not have the Faith, as you say, on the other hand the preoccupation with religious things is never absent even a day from my life." The "preoccupation with religious things" referred to by Proust is reflected also in recent works of nonbelievers, including writer and philosopher Michel Deguy, whose theory of "relics" is intended to give new meaning to what has become unbelievable: "The poet is someone who seeks a re-use for the great theologemes that made and were our great beliefs" (Deguy 2001). Outside of the specifically French tradition, religion appears as an essential question for twentieth-century Francophone writers, including Mongo Beti, Assia Djebar, and Ahmadou Kourouma. The ambiguities pertaining to modern

disenchantment are exemplified notably by Kourouma, as the demystification of African history associated with his novels is coupled with a sanctification of writing which he compares to priesthood (Ouédraogo 2000).

Characteristics

The distinctiveness of this discipline pertains to specificities that are at once linguistic, cultural, historical, and geographic. Today's linguists and Francophone scholars study the different forms of French and diverse literary texts from various countries that share a common history. As stated by Jean-Benoît Nadeau and Julie Barlow, "if French became not only a European but also an African, Asian and American language, it is because French became an important colonial power" (Nadeau and Barlow 2006).

In the eighteenth century, French was recognized as "the universal language." Responding to a question chosen by the Berlin Academy for its essay contest in 1783, Antoine de Rivarol attributed the status of French as the world's *lingua franca* to its clarity: "*If it's not clear, it's not French; if it's not clear, it's still English, Italian, Greek or Latin.*" The reputation of French as a language of exceptional clarity has been perpetuated by authors such as Paul Valéry, stressing its resistance to "composite word formations, facile agreements [and] arbitrary placement of words in sentences." And while having relinquished its former status as the universal language, which is presently that of English, French remains one of the official working languages of world organizations such as the United Nations and the International Olympic Committee.

As related to the area of "Science and Religion," the ideal of purity associated with the French language since the seventeenth century may be viewed in an anthropological or a religious light. Nadeau and Barlow compare purism to "a religion" uniting speakers of French, and refer to the French Academy, whose history is synonymous with that of purism, and whose chief function is to produce a dictionary, as being all about

“consecration”: “If a word enters the Academy’s dictionary, its use is indeed ‘consecrated’” (Nadeau and Barlow 2006).

Relevance to Science and Religion

Scholars of French and Francophone literature and culture often see their discipline as related to religion. A smaller but growing number focus on the relation of literature with science. Seen in a broad perspective, this discipline appears intimately connected with the scholarly area called “Science and Religion.”

The publication of Denis Diderot and Jean le Rond d’Alembert’s *Encyclopedia* during the 1750s became the subject of a controversy in which the philosophical (or scientific) “search for origins” was at odds with the mysteries of religion. Authors such as Voltaire and Paul-Henri Thiry d’Holbach similarly pursued a rationalist critique of religion that was widely echoed in the literature of the late eighteenth century and in the oratory of the French Revolution. The Enlightenment debate opposing philosophy and religion resurfaces during the nineteenth century, for instance, as parody in Flaubert’s *Madame Bovary*, where the priest Bournisien and the pharmacist Homais reflect the waning of belief and the rise of science, or as part of avant-garde aesthetics in Baudelaire, whose critique of faith in scientific progress is coupled with a reflection on religion that should be understood as scientific. The assertion that “nothing upon earth is interesting except religions” is made by an author whose religious views are unorthodox, if not heretical, and for whom the “fanaticism of humility” consisted in “not even [aspiring] to understand religion.”

The pairing of scientific inquiry and religious uncertainty in twentieth-century French novels such as Samuel Beckett’s *Molloy* and Michel Houellebecq’s *The Elementary Particles* is indicative of a spiritual impoverishment that is felt not only in France, but also in other parts of the French-speaking world. Complementing Kourouma’s famous assertion that the suns of Independence “not only unmanned, but also

unmagicked Africa,” late twentieth-century women writers Véronique Tadjo and Werewere Liking respond to the seeming disappearance of traditional belief systems in urban Africa by advocating a return to ritual.

Sources of Authority

The sources of authority for the study of French language and literature are, firstly, literary texts from the Middle Ages to the twenty-first century. In recent decades, attention in this discipline has shifted from strictly literary texts to focus on other media, including newspapers, comic strips, radio, film, and television.

To ask what makes these sources authoritative is to pose the question of canonicity which has been a subject of considerable debate, particularly within American universities, since the 1960s. While critics of the traditional French literary canon typically point to the exclusion of women and minorities, its defenders appeal to the notion of aesthetic value. In light of the preceding section, “[Relevance to Science and Religion](#),” the late twentieth-century literary debate can be seen, as an extension of Enlightenment philosophy’s critique of religion. Just as philosophers questioned the authority of the Holy Scriptures, for instance, in opposing the four canonical Gospels to the apocryphal Gospels, modern literary scholars have questioned the authority of texts they consider to have been arbitrarily imposed to the exclusion of others. In our post-Enlightenment societies, the process of desacralization is more obvious than the opposing but often complementary process of resacralization. That the critique of the established canon is articulated in rational terms may keep us from seeing that the establishment of new canons, or anti-canons, is part of an ongoing “religious” process.

Ethical Principles

The ethical principles that guide this discipline can be placed under the heading of beneficence.

While particularly identified with subdisciplines devoted to advancing the causes of social justice and cultural diversity, such as Francophone studies, feminist studies and gender studies, the discourse of “doing good” is frequently adopted as well by professors of literature and pedagogy. That the rise of moralism (or of utilitarianism) within this discipline has coincided in recent decades with a shift away from literature may be thought of, not as an arbitrary development, but as relating to traditional discussions of literature and morality. The notion that literature would serve the cause of good is antithetical to a tradition exemplified by Baudelaire, who admired Pierre Choderlos de Laclos and the marquis de Sade for their portrayal of evil, or André Gide who said that good sentiments make bad literature. More recently, philosopher Jean-Pierre Dupuy has wondered whether our scientific culture based on rationalist principles has forgotten evil, and Michel Deguy has argued that teaching the knowledge of evil is specifically the role of literature.

Key Values

For most of the twentieth century, the key values of this discipline were the notions of social progress, scientific reason and cultural refinement comprised in what was referred to as “French Civilization.” As explained by Tyler Stovall and Georges Van Den Abbeele, the word *civilization*, “first coined in the eighteenth century by the philosopher Mirabeau to indicate both the reality of organized society and the ideal of human progress, took on what Jean Starobinski has termed a ‘sacred authority’ during the period of the French Revolution and afterwards” (Stovall and Van den Abbeele 2003). Whereas the exportation of French cultural values and intellectual traditions was “institutionalized by the colonial school systems seeking to advance France’s ‘civilizing mission’ throughout its empire,” with the rise of postcolonial and Francophone studies in recent decades, the authority and the objectives of “French Civilization” have been called into question. While continuing to embrace

Universalist Republican principles of social progress, proponents of *la Francophonie* emphasize the consciousness of belonging to an international community and respect for cultural differences.

Conceptualization

Nature/World

This discipline defines nature as, for instance, the phenomena of the physical world as opposed to human beings and human creations or the whole natural world including human beings. Considered in classical aesthetics as a model to be imitated by art, nature takes on new significance in Romanticism where its diversity and immensity are seen as a reflection of the human soul. The scientific “study of nature” characteristic of nineteenth-century realism and naturalism stands in contrast to the predominance of mystery in symbolism. Opposing scientific and religious views of nature are equally prevalent in twentieth-century literature.

Human Being

The term *human being* (*être humain*) was traditionally synonymous with *man* (*l’homme*), defined as a rational being, and referring either to particular individuals irrespective of sex, or to the human race or species personified as an individual. In keeping with modern values inherited from the French Revolution, this discipline typically conceives of human beings in terms of individual rights and social justice. After the French National Assembly’s *Declaration of the Rights of Man* in 1789, Olympe de Gouges published a *Declaration of the Rights of Woman*. The influence of feminism during recent decades has resulted in the gendering, or ungendering, of language pertaining to individuals in accordance with modern egalitarian ideals.

Life (and Origins of)/Death

The conception of life as depicted in literary works varies widely according to the period, the culture, and the beliefs of a given author.

Historian Philippe Ariès relies extensively on references to French literature in outlining a shift in Western attitudes from the Middle Ages when death was communal and public in character to the twentieth century when death had become more private and discrete. Eulogizing Hugo upon his induction into the French Academy in 1887, Leconte de Lisle attributes what he refers to as Hugo's disdain for scientific attempts "to explain the origins of life" to his faith in the "arbitrary dogmas" of religion.

Reality

An illustrious line of modern French writers have sought to question and reinvent our understanding of reality. Proust's observation on the style of Flaubert, who, "by his entirely new and personal usage of the past definite, the past indefinite, the present participle, and of certain pronouns and prepositions," is said to have "renewed our vision of things almost to the same extent as Kant, with his Categories, renewed our perception of the reality of the external world" is echoed in the writings and theories of later experimental authors, including those associated with the *Nouveau Roman* in the 1950s.

Knowledge

This discipline usually conceives of knowledge as corresponding to areas of specialization that are defined either historically (i.e., as relating to a period or century) or geographically (i.e., in terms of a country or region). The knowledge of literature associated with fields of expertise is, nonetheless, distinct from the question of knowledge in literature. With respect to knowledge, literature is often contrasted with science in ways that recall the opposition of science and religion. If, for instance, literary knowledge appears questionable from a scientific perspective, the foundations of scientific knowledge have also been questioned by literary, and particularly postmodern, critics. The association of knowledge with initiation rituals pervades a wide array of French and Francophone literary texts from the eighteenth century to the present.

Truth

The first definition of the word *vérité* in the original edition of the *Dictionary of the French Academy* (1694) is: "First truth, the essential truth. God is the principle of all truth." The second definition is: "Conformity of what one says or thinks with what actually is." In the fifth edition of this dictionary in 1798, the order is reversed. The first definition of *vérité* is: "Conformity of the idea with its object." The theological meaning is mentioned only later, along with several other meanings, including an aesthetic meaning used in referring to painting or poetry. The erosion of essential or divine truth during the eighteenth century is followed in the nineteenth century by its recuperation in literature, notably with Hugo and Baudelaire. Late twentieth-century critical theories, from structuralism to postmodernism, emphasize the arbitrariness of sign systems in rejecting the notion of absolute truth.

Perception

Examining and redefining modes of perception has been a main preoccupation in French and Francophone literature, particularly since the beginning of the twentieth century. In *Remembrance of Things Past*, Proust adopts a narrative technique which he attributes to Madame de Sévigné and Dostoevsky. "Instead of presenting things in their logical sequence, that is to say beginning with the cause," these authors show us "first of all the illusion that strikes us." Nathalie Sarraute would later borrow the term "tropisms" from biology to describe "certain interior actions," "the indefinable movements that slip by very rapidly at the limits of our consciousness," and which are "at the origin of our gestures, of our words."

Time

A variety of literary texts, from Romanticism through the twentieth century, reflect an opposition between traditional notions of cyclical time and the modern Western idea of linear time. Kourouma's *The Suns of Independence* is punctuated by references to cyclical time, which is the time of myth and ritual associated with the

main character Fama's place of origin, Togobala, in contrast with the anonymous westernized "capital city." The contrast of linear and cyclical time is, moreover, contained in Kourouma's title, as the Malinke expression, "the suns of Independence," evoking the cycles of nature, corresponds to the historical "era of Independence" in French. A similar juxtaposition of cyclical and linear time linking myth and ritual to a rural place of origin is found in Gérard de Nerval's novella *Sylvie*.

Consciousness

The French word *conscience* is translated into English either as *conscience* or as *consciousness*. The philosophical sense (that is, *consciousness*) referring to the awareness of one's existence, as distinct from the preceding moral sense, dates from the Enlightenment, and is particularly associated with the writings of Rousseau. A variety of nineteenth- and twentieth-century aesthetic theories explain literary creation as a process of bringing the unconscious to consciousness. The word *consciousness* is used by critics in Francophone studies and cultural studies in reference to race, gender, and alterity.

Rationality/Reason

Rationality and reason are particularly associated with Enlightenment philosophy where reason, understood as a mental faculty or as a guiding principle, is routinely opposed to faith and religion. As stated in the article "Philosopher" from Diderot and d'Alembert's *Encyclopedia*, "Reason is to a philosopher what grace is to a Christian. Grace impels the Christian to act, reason impels the philosopher." The reliance on reason in the Enlightenment critique of religion results not only in the de-Christianization of French society but also, paradoxically, in the sacralization of "Reason," notably as the object of an official cult during the French Revolution. The questioning or rejection of Enlightenment rationality pervades modern literary movements from Romanticism to Surrealism and has more recently been associated with postmodern philosophy.

Mystery

The attitude of eighteenth-century French philosophy, which viewed mystery not as something incomprehensible, but rather as something which has not yet been understood, is epitomized by the opening sentence of Diderot's *The History and the Secret of Painting in Wax*: "Nothing is more contrary to the progress of knowledge than mystery." The later appropriation of mystery in aesthetics, for instance, by Mallarmé – who wrote that "whatever is sacred, whatever is to remain sacred, must be clothed in mystery," and that "art has its own mysteries" – is considered not as a reaction against, but rather as a consequence of, scientific progress, with art appearing as a substitute for religion in a disenchanted world.

Relevant Themes

The evolution of French language and literature from the Middle Ages to the present reflects a variety of different phases in the thinking of French speakers with respect to science and religion. Additional relevant issues, themes, or concepts within this discipline are virtually limitless. From the historical perspective outlined in this article, magic appears as a particularly important issue. Depending on the period, magic is opposed to science and associated with religion, or associated with science and opposed by religion. The waning belief in magic during the Enlightenment parallels the rise of its metaphorical usage in art criticism and literature.

Related Terms

[German philology](#); [German studies](#); [Germanistik](#)

Description

The discipline has a double focus of interest: It deals with both the material of human utterance and its results. The linguistic approach bears close resemblances to sciences like anatomy, neurology, statistics, or geography, while the

study of literature is related to art history, cultural studies, and literary criticism. The hermeneutic challenge of literature unites the scope of the field of study with the problems discussed in the classical philologies, philosophy, and theology. The discipline as a whole draws on specific subdisciplines (rhetorics, poetics, emblematics, codicology, etc.). Moreover, it is linked to neighboring fields, such as cultural, historical, artistic, theological, or linguistic studies.

Founded in the early nineteenth century (initiated by Jacob and Wilhelm Grimm in the framework of German Romanticism and Nationalism), the field of study was historically oriented and aimed in a distinctly antiquarian manner at reconstructing “das deutsche Altertum” (*German antiquity*). Since then and especially in the postwar twentieth century, scholars have taken up new issues and widened their perspectives. The linguistic part of the discipline analyzes the systematics of the German language in respect to articulation and writing (phonology, orthography) and of its components, words (morphology) and sentences (syntax). The production and communication of meaning are investigated in terms of semantics and pragmatics; the components of the German language are examined by lexicography, phraseology, and dialectology. All these aspects are treated in synchronic view as appearing in certain historical periods or regional and social variants, as well as in diachronic development from Indo-Germanic roots to present German within certain language families (Weimar 1989/2003; Gardt 1999).

Reflecting the historical evolution of their subject, larger university departments of German language and literature are mostly divided into at least two subdepartments, mediaeval (and sometimes Renaissance) studies and Neue deutsche Literatur (“new” referring to the evolution of Neuhochdeutsch, the present German, which basically emerged at the beginning of the Renaissance).

As migration movements have increased, the didactics of German language and literature have widened their focus and explored teaching techniques for younger and older learners whose first

language is not German. This has led to a still growing number of departments for German as a foreign or second language.

After the entanglement of the discipline in fascist ideology during Hitler's reign (welcomed by many Germanisten as a proof of usefulness of their studies (König 2003)), postwar scholars developed new approaches to the study of German language and literature, including Europeanness, structuralism, social history, intertextuality, psychology, and psychoanalysis. These developments coincided with a similar paradigm change in the humanities in general. Recent research intensively draws on theories elaborated in cultural studies. Media studies investigate the history of text circulation ranging historically from orality to electronic virtuality. Indeed, there is a strong interest in all forms of culturality, especially gender constructions, relation of identity and otherness, and consequences of the performative turn (Bachmann-Medick 2009) for our understanding of language and its artifacts. The themes discussed at the last international congress for German language and literature (Paris 2005) ranged from Jiddish via German as a foreign language, empirical basis of grammar research, cultural studies as opposed to classical philology, migration, media, national vs. global cultures, cultural topographies, gender as cultural conflict, and classicisms to the Europeanness in and of German literature (2007/2008).

Self-identification

Science

For the study of German language and literature, there is no clear distinction between science and religion but an interwoven relationship. Basically and normatively, modern philology in general is the product of academic diversification during the Enlightenment, when theology lost its potential as the leading discipline. Focusing on German antiquity, first German philologists had to find, understand, edit, and comment on religious texts for lack of others. However, they were not applying religious but historical and philological

tools. Nevertheless, all vernacular-based new philologies drew heavily and exclusively from the apparatus of biblical scholarship in using the techniques of securing, editing, and commenting on texts. Moreover, it was the transfer of religious thinking to secular objects that brought about the modern hermeneutics of art.

Characteristics

By definition, the discipline concentrates on German language and literature or, in a broader sense, on German culture, as opposed to other language-oriented studies within the humanities. Historical and systematical research on German cannot be achieved without a comparative look at other languages and cultures. Therefore, German studies have to investigate not only the linguistic and literary influence of neighboring modern European cultures but also the Greek and Roman classics that shaped European knowledge and art. At present, language interference and German immigrant writing, especially from Islamic background, are matters of growing interest. The close relation to other modern philologies and the almost identical scholarly activities have led to a constant interdisciplinary discussion of problems and methods and to a still growing international, if not yet intercultural, exchange of trends.

Relevance to Science and Religion

Except for linguistics with its tradition of experimental and empirical research, scholars in the German-speaking countries seem to shy away from dealing too closely with hard sciences like neurobiology or brain research. Here, the distinction between the traditional concept of "Geisteswissenschaften" (humanities) and, as opposed to, "Naturwissenschaften" (sciences), expounded by Wilhelm Dilthey in the nineteenth century, still influences the view of these as two different academic cultures, Geisteswissenschaften being postulated as a corrective of the (moral, ethical, philosophical) shortcomings

of hard sciences: “Je moderner die moderne Welt wird, desto unvermeidlicher werden die Geisteswissenschaften” (*the more modern the world, the more necessary the humanities*) (Marquard 1985/1986).

On the other hand, scholars were for long periods equally reluctant to deal with religious matters. The Weimar classics propagated and created literature on the basis of “idealistic” art and aesthetical autonomy, which meant a strict refusal of all attachments outside of art itself. After the deep contamination of the discipline with Nazi ideology, “ideological” texts of all sorts were a no-go area for at least the postwar generation of scholars (Conrady and Polenz 1967). Meanwhile, the cultural turn has drawn new attention to how art is intermingled with religion and ideology and facilitated a more flexible and pragmatic approach to all texts, producing what we call meaning and cultural orientation.

Sources of Authority

Like elsewhere in the scientific community, high quotation scores generate authority. It is assumed that the impact of publications correlates with the importance of the journal or the publishing house. At the same time, there are distinctive networks propagating certain fields or approaches and competing in their aim to establish their ideas as a new state of the art. Research funding is usually granted to those projects drawing on emerging theories in the humanities. This means that theoretical debates stimulate research quite directly, at least in the German-speaking countries with their system of almost exclusively public research funding.

Ethical Principles

German studies respect individual authorship of text and thought to the point that coauthorship in research is rather the exception than the rule. Presumably, this owes also to a certain individualism scholars still tend to cherish. A strong

awareness of the fact that the academic field was playing a major part in spreading Nazi ideology in the field of education has led to changes in German studies that brought the discipline closer to the other modern languages and their achievements.

Key Values

The discipline is guided by philological accuracy in relation to the text and historical precision with regard to its origin and its communicative circumstances. Scholars have to keep in mind the relation between text and speaker (or, in literature, author) and between text and media and the encoding of the text. Their research is bound to exactness in applying the methods and terms of the discipline. Great attention lies on the fact that languages shape and transport social constructions like gender or history.

Conceptualization

The linguistic branch of the discipline regards nature as the organic, neurological, and environmental condition of human speaking. Literature, by contrast, depicts *world and nature* as products of human apperception and its cultural representation. In explaining the relation between comprehension and utterance, the discipline applies the means of philosophical and anthropological models (I. Kant, S. Freud). Language and literature form a central part of the social construction of meaning and of cultural identities. The study of German language and literature has helped to shape and foster the concept of *Deutschtum* (“*Germanness*”) from Romantic nationalism via Nazi misuse of language and art to German reunification and the search for a cultural identity within the European union.

As language and literature deal with the basic facts of *human existence*, this includes deliberations on *life and death*. Death plays a central role in German literature from the mediaeval Dances of Death to authors of our days (e.g., Thomas Bernhard, Hermann Burger, etc.), which can be

traced back to the fact that Christian religions shaped the culture of central Europe.

The questions whether and, if so, how art can depict *reality* have been central to art theories since Greek and Roman antiquity. Discussing these issues under the heading *mimesis*, the German debate has led to a specific development. G. E. Lessing stressed the difference between the visual arts and drama and promoted the idea of educating the theater public by training their ability to perceive compassion in others. Friedrich Schiller, on the other hand, argued that reality was to be esthetically transformed. His concept, which became known as “*Idealisierungskunst*” (*idealizing art*), opened the way for the Classical period of German literature around 1800.

In the twentieth century, the so-called linguistic turn (Bachmann-Medick 2009) has linked *knowledge* to the conditions of language structures that provide the pattern of utterance. This nominalist concept can be traced back to at least the nineteenth century in the German philosophical tradition, when Friedrich Nietzsche spoke of *truth* as “*ein bewegliches Feld von Metaphern*” (*a moveable field of metaphors*) (Nietzsche 1967). At present, it seems to be rather uncontroversial to conceive of truth as a discursive effect engendered by certain historical and generative rules open to scientific reconstruction (Brandt 2004).

The discipline concentrates on visual and acoustical *perceptions* generated by the respective media. Hence, German studies deal with the history of listening and reading, of speaking and orating not only in printed media but also in folk songs and libretti. Tactile perception is considered less important, although human heartbeat and breathing are elements of the phenomenon of metrically organized poetical expression.

In relating their findings to the concepts of *time*, *human being*, and *human consciousness*, scholars have adapted the models of historical and scientific research.

While both language and literature draw not only on reason but also on sources that elude rational control, science is considered to rely solely on *reason and rationality*. Putting aside

in presentations, papers or books is looked upon as unscientific sentimentalism, dilettantism, or partiality. *Mystery* plays no role in German academic discourse but as an effect is used in popular and trivial literature since the late eighteenth century. Unsolved problems of understanding in language and literature are regarded either as still to be elucidated in future research or as part of the uncertainties language produces on principle, and even more so in works of art. The former is the position of classical modernity relying on the progress of knowledge, the latter the understanding of postmodernism and post-structuralism.

Description

Hebrew is a Semitic language which developed in the Near East during the latter half of the second millennium B.C.E. in an area between the River Jordan and the Mediterranean known as Canaan. The language is named after Ever (Eber, Genesis 11:14), a biblical ancestor of Abraham, the patriarch who would become the father of the Hebrew/Israelite/Jewish nation.

Hebrew was defined and accepted as a sacred language by its earliest practitioners and scribes as it was viewed as the language spoken by the Biblical God when creating the world and when communicating with the people of Israel, their leaders, their prophets, and the occasional lay people who were chosen to carry forth a divine plan. As a sacred language, it was used in liturgy

and for the expression of doctrine, thus becoming the holy language of Judaism and its practice.

However, evidence suggests that Hebrew served from its inception as a vernacular, spoken language, as well as the written language of the Hebrew Bible (Biblical Hebrew). In both functions, the language played an important role in shaping the identity and the culture of the Jewish people. This phenomenon continued as Hebrew served not only as the daily language in the Land of Israel until the destruction of the Second Temple (70 C.E.) and the final exile by the Romans in 135 C.E. (Rabbinic Hebrew) but also as a language that followed Jews into their places of exile. Throughout Jewish existence in the diaspora, which would last until the creation of the modern State of Israel (135–1948 C.E.), Hebrew maintained its functions as a sacred language expressing the being and the essence of a monotheistic God, a language of prayer and ritual, a legal language, and a language of commerce connecting the Jewish communities throughout the world. Medieval times witnessed the use of Hebrew as a language of philosophy, poetry, and literature (Medieval Hebrew), while modernity and Jewish nationalism inspired a return to Hebrew as the renewed marker of a political and cultural entity bound by a shared language (Modern Hebrew).

This history that spans more than 3,000 years also contains constant exposure to the languages of the peoples wherein the Jews dwelled. Linguistic evidence, however, indicates that Hebrew remained substantially the same language in its morphology, phonology, and syntax throughout the years. The Hebrew which is used today in Israel derives its structure and vocabulary from all the periods preceding the creation of the modern State of Israel and its expansion and development through a revival movement driven by the man considered the father of Modern Hebrew language, Eliezer Ben-Yehudah (1858–1922).

Hebrew Literature

The range of literary genres found in the Hebrew Bible enabled the creation of both secular and

religious literature throughout Jewish history, despite the interruption of the function of Hebrew as a vernacular. Included in the 24 books of the Hebrew Bible were not only mythical stories such as The Creation of the World and the Flood but also the story of the Tower of Babel that explained the existence of languages other than God's original one (*Genesis* 11). Erotic poetry found its place in the *Song of Songs* (The Song of Solomon); wisdom literature in *Job* and *Ecclesiastics*; historical tales in *Chronicles*, *Ezra*, and *Nehemiah*; prayers and hymns in *Psalms*; law and theology in *Exodus* and *Leviticus*; and pathos, revelation, and redemption literature in *The Prophets* and in the Apocryphal *Dead Sea Scrolls*.

Rabbinic literature added commentaries and extrapolations of Biblical texts to the canon of Jewish literature, as did Medieval writers who also wrote scientific, mystical, and philosophical treatises in Hebrew. Enlightenment and modernity led to the revival of secular literature which included poetry, prose, and even drama, leading to the revival of the vernacular. The relationship between Jews and their language now included the seeds of aesthetic as well as religious experiences.

Hebrew was and still is a subject of linguistic, theological, historical, and literary inquiries because of its unique position as the original holy language of monotheism. The study of Hebrew grammar, syntax, and morphology is pursued by scholars and believers alike striving to glean meaning from sacred texts that shaped Judaism as well as early Christianity and Islam. The Hebrew alphabet became a signifier of contents believed to be hidden and theologically significant to pursuers of mysticism. Modern researchers engage in contextual (Aaron 1990, 2000), comparative (Saenz-Badillos 1993), and historical inquiries (Rabin 1969–1970; Weinberg 1981; Kutscher 1982). *The Academy of the Hebrew Language in Israel*, which was founded in 1953 to provide a continuing supply of (renewed) vocabulary as well as control over pronunciation and grammar, still publishes word

lists approved by its members (<http://hebrew-academy.huji.ac.il/english.html>). Contemporary Israeli artists engage in creating visual, plastic, and theatrical representations of their relationship with the constantly evolving language and its roots in the sacred (Aviv, Nurit: *Langue sacrée', langue parle'*) (<http://www.cinemotions.com/modules/Films/fiche/36361/Langue-sacree-langue-parlee.html>).

Sacred and secular, contemporary and ancient, the Hebrew language continues to evolve and engage native speakers as well as curious outsiders, striving to understand and define its impact on Jewish and Israeli identities as well as on Western culture.

Description

Spanish language and literature, broadly defined, have a long history of engagement with religious and scientific thought. The Iberian Peninsula was an important Roman colony and home to well-known scholars of Antiquity including Seneca. The Middle Ages witnessed a cultural flourishing in Iberia marked by significant advancements in literature, language study, and in scientific and religious thought, producing some of the most influential Arab and Jewish thinkers of the period. Medieval and early modern Christian leaders and scholars, in both the Iberian Peninsula and beyond, were deeply indebted to the work of these Muslim and Jewish scholars from Spain, and their interpretations of and original writings based on the ideas of Aristotle bear the mark of these earlier generations of Arab and Jewish philosophers and exegetes. The age of Spanish imperialism and conquest (sixteenth–eighteenth centuries) is characterized by the humanism of Western Europe, but also the realities, aspirations and even anxieties of imperial expansion, framed by many Spanish intellectuals of the period as an expression of the will of God. The early modern period also witnessed advances in the study of the Spanish language, as it became a tool for proselytization in new colonial territories. The fall of the Spanish Empire and loss of its colonies provoked a profound crisis in Spanish intellectual circles, and many Spanish thinkers of

the nineteenth and early twentieth centuries looked to the literary production of earlier periods both for the reasons of the waning of Spanish political and cultural influence and for the creation of a modern national “Spanish” European identity. Nineteenth- and twentieth-century intellectuals in the former Spanish colonies of Latin America adopted the discourses of the European Enlightenment as they forged literatures of independence. The twentieth century is defined in Spain by the fascist dictatorship of Francisco Franco and much of the literary production of the period reflects his vision of an orthodox Catholic nation. Since Franco’s death in 1975 religion has played a significantly lesser role in Spanish literature as Spain has taken the forefront among European nations in innovative scientific research. However, increased immigration from Africa, the Madrid train bombings of 2004, and Spanish involvement in Iraq as an ally of the USA precipitated a pro-Christian, anti-Islamic reaction among some Spanish scholars and in public discourse.

Self-Identification

While until the twentieth century scholars working on Spanish cultural production did not (necessarily) divorce language study from literary studies, today the study of Spanish language and literature is conducted in large part by experts trained on the one hand in linguistics or, on the other, in literary and cultural studies. The former study the formal aspects of the Spanish language, its development, dialectical and regional differences, and the social contexts of its speakers. The latter specialize in the literary productions of specific regional or national literatures in Spanish (e.g., Latin American, Peninsular, or more specifically Argentine, Mexican, etc.), and their training is based on philological textual criticism and/or literary theory and cultural studies. Today linguists who specialize on the study of the Spanish language generally identify their work as scientific, and their scholarly inquiries are based

on the scientific principles of linguistics, while literature scholars generally self-identify as nonscientific, and align themselves with the humanities and arts. However, this has not always been the case, and many of the pioneers of the study of Spanish language, literature and history, such as Marcelino Menéndez y Pelayo, Claudio Sánchez Albornoz, and Ramón Menéndez Pidal, conceived of their studies of early Spanish literary works and history as scientific (positivist and teleological) – an attitude they shared with European intellectuals of the nineteenth and early twentieth centuries in France and Germany. Even today in Spain literary studies are often considered scientific in nature, as evidenced by the existence of the prestigious Consejo Superior de Investigaciones Científicas (CSIC), a state agency designed to foster scientific and technological investigation and that is a major economic and cultural contributor to Spanish literary scholars and linguists. The CSIC has its origins in and remains closely identified with the Centro de Estudios Históricos directed by the philologist Ramón Menéndez Pidal.

Relevance to Science and Religion

In earlier periods, particularly in the twelfth through sixteenth centuries, language use and literary production in Spain was often determined in large part by religious identity. The theological debates of the Middle Ages, which often engaged the role of the natural sciences (astronomy, physics, and math) in society, found expression in all the major languages of the Peninsula and in a number of what we would consider literary texts, including prose fiction (Arabic *maqamat* and Romance *libros de caballerías*), poetic and song texts (*diwan* and *cancioneros*), and didactic treatises (Arabic *risalat* and Latin *ars*) etc. Muslim scholars writing in Arabic, such as the eleventh century writer Abu Muhammad ‘Ali ibn Ahmad ibn Sàid Ibn Hazm (994–1064) were familiar with the beliefs of Iberians of other confessional identities, particularly Jews and Christians. Ibn Hazm, who lived through the final years of the Umayyad caliphate in Cordoba

and witnessed the political upheavals that followed, engaged in a debate with the learned Jewish courtier and writer Samuel ha-Nagid over the positive and negative aspects of Judaism and Islam. Ibn Hazm also composed a treatise on the history of religion, *The Book of Religions and Sects* – a work that has survived and is considered one of, if not the first comparative study of religion. Both Ibn Hazm and Ha-Nagid are considered today as two of the foremost poets of Iberia during the Middle Ages. During the Taifa period of the twelfth century while the caliphate fractured into many smaller regional kingdoms or Taifas, the newly popularized rhymed prose *maqamat* often explored points of religious doctrine by repeatedly confronting the protagonist (and thus reader) with a dilemma that forces him/her to examine the nature of organized religion and belief (e.g., fictional accounts of street preachers fleecing the ignorant populace or repentant holy men imbibing in taverns) and the more weighty and abstract points of dogma (e.g., the role of free will and/or predestination). The latter was a topic of much debate among Arabic theologians, and particularly so for the group known as the Brethren of Purity who had many adherents in the Taifa kingdom of Zaragoza. Even after the more fundamentalist Almoravids and Almohads invaded the Peninsula in the eleventh and twelfth centuries under the pretext of restoring Islamic orthodoxy, we find Andalusí thinkers, such as Abu Bakr Muhammad ibn Abd al-Malik ibn Muhammad Ibn Tufayl (1105–1185), similarly exploring man’s natural proclivity for religious belief in his fictional tale, *Hayy ibn Yaqzan*, a story later translated into Latin and inspiration for both Daniel Defoe’s *Robinson Crusoe* and John Locke’s concept of the *tabula rasa*. It is, in fact, out of this intellectual universe, one in which Islamic thinkers had been grappling with the ways in which Aristotelian and neo-Platonic ideas about skepticism and the natural world could be reconciled to religious faith, that the two greatest intellectuals of medieval Spain emerged, Ibn Rushd and Maimonides. Ibn Tufayl recommended to his Almohad patron that the great philosopher, theologian and commentator on Aristotle, Ibn Rushd

(Averroes) (1126–1198), serve as his successor at court. Ibn Rushd wrote on many topics, including mathematics, law, music, grammar, and most notably philosophy. His best-known and most influential work, *The Incoherence of the Incoherence*, was a defense of Aristotelian rationalism in response to the work of the earlier Muslim scholar, Avicenna. Like Ibn Rushd, the Jewish thinker Maimonides (1135–1204), was also a medical doctor, and in his own philosophic work sought to reconcile Aristotelian thought with the Jewish faith. Maimonides continues to be regarded as one of the fathers of modern Judaism.

The Aristotelian rationalism of Ibn Rushd and Maimonides once translated from the Arabic and Hebrew made great waves among the scholastics of Northern Europe, most notably in the ideas of Peter Abelard and Thomas Aquinas. In addition to the philosophical, theological, and scientific methodology transmitted from Muslim Spain to Western Latin Europe, the translation process that allowed such transmission merits mention as one of the most important contributions of Spanish language and literature to world thought. This translation activity in the eleventh, twelfth, and thirteenth centuries established Toledo as an intellectual center known across Europe as a place where scholars could learn Arabic and have access to Arabic scientific and religious texts.

Medieval Christian scholars in Spain did, like their counterparts in the rest of Europe, use Latin as their main language of official culture. However, the Castilian king Alfonso X, known as “the Learned,” commissioned several translation projects and original works in the Romance vernacular (mostly in nascent Castilian) in order to establish Spanish as the official language of culture and science in the Peninsula. Alfonsine translations include Arab philosophical, religious, mathematical, astronomical, and astrological treatises, including Aristotle’s *Poridat de las poridades* (*Secretum Secretorum*) and Ibn Haitham (Alhazen)’s *Configuración del mundo* (Latin *Liber de mundo et coelo*), which would have great impact upon later Western European intellectuals’ (such as Albertus Magnus, Robert Grosseteste, Copernicus, Roger Bacon)

understanding of the world. These Alfonsine translations built upon an already established culture of translation encouraged by earlier intellectuals, such as the archbishop of Toledo, Raimundo (d. 1152 C.E.), who was the patron of several scholars, including Gerard de Cremona whose translations of Aristotle’s works were informed by the commentaries of Arab thinkers such as al-Farabi and Ibn Rushd. Several of these translators, including Adelard of Bath and Dominicus Gundisalvus also composed original philosophical works in Latin (*Questiones naturales perdifficiles*, *De anima*, *De processione mundi*) that would today be considered scientific inquiries into the natural world. These scholars also translated texts by Archimedes, Ptolemy, and Euclid from Arabic into Latin. Their translations also include treatises on the astrolabe and mathematics penned by Arab and Jewish scholars.

Translations of imaginative works, although fewer in number, are nevertheless very important and offer some of the first examples of fictional prose literature in the Castilian language. Before assuming the throne, Alfonso had the tale collection, *Calila wa Dimna*, which traces its origins to the Sanskrit Panchatantra translated into Castilian. Alfonso’s younger brother Fadrique similarly commissioned the translation of *Sendebat*, another frame tale with Eastern origins that later morphed in the Western tradition into the *Seven Sages of Rome*. Both of these works of imaginative fiction are centrally concerned with the processes through which wisdom is transmitted and reflect the ethos of East to West translation occurring in Iberia. A witness and product of this cultural milieu, Moshe Sefardí (who later converted to Christianity and took the name of Petrus Alfonsi b. 1106) physician to both Alfonso el Batallador and Henry I of England, exemplifies how the legacy of these translations and the Arab and Jewish knowledge they conveyed was transferred to the rest of Europe. Petrus Alfonsi penned the *Disciplina clericalis*, one of the most important known works to adapt Muslim and Jewish literary narrative content and forms to Western Latin culture. This work, ironically, became a basic source from which preachers

across Europe could select appropriate anecdotes to illustrate their sermons.

The growing cultural and political strength of the Iberian Church is reflected in the literature of the thirteenth and early fourteenth centuries. King Alfonso's nephew, the noted author Don Juan Manuel, portrayed the growing tension in Iberia between the ecclesiastical Latinate culture of the Church and the centuries-long tradition of Arabized Aristotelian scientific inquiry in his short narrative, "Ejemplo XI. De lo que aconteció a un dean de Santiago con don Illán el gran maestro que moraba en Toledo," included in his collection *El Conde Lucanor*, a work based in part on Arab and Hebrew narrative collections circulating in the Iberian Peninsula. In this fictional narrative Juan Manuel problematizes the conflicting epistemologies of the Church and the natural sciences, asking his reading public to question the stereotypes of the Church and Churchmen as purveyors of morality and their attempts to demonize those who pursue study of the natural sciences as necromancers. Such a narrative is an echo of earlier Arabic and Hebrew fictional narratives composed in the Peninsula that ask the reader to question not only the hypocrisy of religious leaders, but also the deeper theological import of the doctrines of free will and predestination.

These themes also dominate the work of the Catalan intellectual Ramón Llull (1232–1315), a contemporary of Alfonso X, whose works in Latin and Catalan defy contemporary classification because they deal with such disparate subject matter as theological debate, mathematics, fictional romance, and logic. Llull, who was familiar with both the Arabic and Latinate intellectual traditions, exemplifies how literary, linguistic, scientific and religious knowledge were tightly woven and interdependent in medieval Spanish culture. Like Alfonso X and the intellectuals of the Toledo milieu, Llull was also intensely interested in translation as a vehicle of religious and political power. Llull devised among many other things "thinking machines" or *Lulian circles* in which theological and philosophical principals could be combined in an attempt to systematize knowledge. Llull, a pioneer in early vernacular

literature, is considered by some twentieth-century computer scientists as a founding father of the field.

While Llull's work, mostly written in Catalan, was read into the early modern period, the unification of Spanish lands under the Castilian crown established the Castilian dialect as the predominant language of the Iberian Peninsula. The humanist and professor of poetry and grammar, Antonio de Nebrija (1441–1522), wrote the *Gramática de la lengua castellana* in 1492. This work was not only the first grammar of Castilian, but of any Romance dialect and marks Castilian as the official language of the Crown. Fifteenth- and sixteenth-century Peninsular literature was predominated by poetry and the collection of songbooks or *cancioneros*. These songbooks were compiled under the direction of noblemen and often the Crown – Juan II and Isabel la Católica were two of the most important patrons of these poetry collections. Some of the poets whose works are included in these collections were of Jewish origins and the subject of confessional and national identity is a pervasive topic in their work. One of the earliest of these collections, the *Cancionero de Baena*, opens with a poetic exchange between unidentified rabbis and the *converso* poet Pero Ferrús regarding the unity of God and the true faith. This poetry also reveals Spanish intellectuals' engagement with the humanistic inquiry and scientific investigations of Renaissance Italy. Juan de Mena's allegorical poem *Laberinto de fortuna*, for example, outlines in lengthy asides contemporary theories of geography, astrology, and natural philosophy.

The Castilian dialect subsequently expanded into the Americas where it became the language of religious conversion literature written for the indigenous population. A well-known example of the latter is "Divino Narcisco," an *auto sacramental* or religious drama by the colonial Mexican author, Sor Juana Inés de la Cruz (c. 1650–1695). Castilian also became the language of many ecclesiastical treatises concerning the rights of the indigenous peoples, which often focused on their humanity and religious nature, for example, Bartolomé de las Casas' (1484–1566) *Breve relación de la*

destrucción de la Indias. Like other Spanish thinkers of the early modern period, Bartolomé de las Casas based his philosophical attempts to fit new indigenous peoples into the Spanish conception of the world in part on his understanding of Aristotle's hierarchy of living creatures, which in turn is a legacy of medieval Iberian Arab and Jewish philosophers.

In the best known work the Spanish imperial "Golden Age," and possibly of Spanish literature, Miguel de Cervantes' (1547–1616) *Don Quijote*, the history of the Muslims in Spain and the fate of their descendants living under Christian rule, the *moriscos*, is the subject of several chapters (Cide Hamete I:9, Zoraida 1:40–42, Ricote 2:34 and his daughter 2:63 etc.). Scholars such as Américo Castro have suggested that Cervantes may have been a *converso* – a descendant of Jews – and that his early training by a follower of the ideas of Erasmus are reflected in his literary works. Others, though, feel that Cervantes' apparent satires of the Church, for example, the burning of the library in *Don Quijote*, which satirizes the inquisitorial *autos-de-fe* was done for comic effect rather than theological critique.

Characteristics

More than any other Contemporary European country, Spain's Muslim and Jewish past has continued into the modern era to shape, in part, its relationship to religion and to the modern perception that a nation's identity as a "modern" state is defined in part by its level of scientific advancement. For the early twentieth-century philologist, Menéndez Pidal, the evolution of the Castilian language and the thriving oral ballad traditions of the Peninsula were proof of the long history of a Spanish national identity as expressed in popular culture. Menéndez Pidal's friend and intellectual peer, Miguel de Unamuno (1864–1936), like the other members of the literary and generational group with whom he is most closely identified, the so-called Generation of '98 (including Antonio Machado and Pío Baroja) and like other European intellectuals of the moment, was intellectually engaged in the concept of

nationalism. The writers of this generation explore in their fictional and poetic writings the role of the Catholic faith as a constituent part of the Spanish nation. One of the best examples of the latter is Miguel de Unamuno's short narrative *San Manuel Bueno, mártir*, which portrays the metaphysical suffering of a parish priest plagued by skeptical rationalism whose own atheism is the source of his extraordinary humanitarianism. Unamuno – whose modern skepticism seemingly tended toward the agnostic or atheist – nevertheless seeks in this and other fictional works to explore what role Spanish religious beliefs and practices played in the fall of the Spanish Empire and what role they should play in the future of Spain. Trained as a medical doctor, Pío Baroja, another member of the Generation of '98, was openly anticlerical and in his fiction presents traditional Spanish Catholicism as a major contributing factor to Spain's "backwardness" and inability to engage in the modern "scientific" society of industrialized Northern Europe. Gregorio Marañón (1881–1960), a medical doctor and writer, who was active in the first part of the twentieth century, combined science and humanistic inquiry in what he described as "biological essays," physiopathological profiles of famous historical figures.

While twentieth-century thinkers such as Unamuno privileged Catholicism in their attempts to establish and define modern Spanish identity, others such as Américo Castro (1885–1972) looked instead to the medieval coexistence or *convivencia* of Muslims, Jews, and Christians to define modern Spanish identity. Castro, an exile from Franco's Spain, worked first in Argentina, and later in the United States. Castro's exile, like that of the Spanish thinkers such as Menéndez Pidal and Sánchez Albornoz, shaped the way Spanish language and literature was and continues to be studied in the Americas. The impact of the legacy of medieval Muslim and Jewish thinkers on Spanish language and literature – the subject of Castro's scholarship – is also the subject of his contemporaries, such as the Argentine writer Jorge Luis Borges. Borges composed short fictional narratives that wrangled with the questions of contemporary theoretical

physics and logic, but often did so in the context of Spain's past. Protagonists of his narratives include medieval intellectuals who, as discussed above, used fiction as a vehicle to investigate the natural world. Some of his stories explore how Muslim, Jewish, and Christian thinkers of Spain (including Ibn Rushd in "La Busca de Averroes," Maimonides in "Milagro secreto," Juan Manuel "El Brujo postergado," and Ramón Llull in *Otras inquisiciones*) were pioneers in philosophy, astronomy, mathematics, and translation. Certain of his fictional narratives such as "El jardín de senderos que se bifurcan" and the "Biblioteca de Babel" question the nature of reality, and suggest the possibility of multiple realities. Borges has become a champion of scholars of both Boolean logic and hypertext. The Chilean Roberto Bolaño's work, like that of Borges, examines, among other subjects, the history of Catholicism in Latin American history. The fiction of other Latin American authors such as Alejo Carpentier (b. Cuba 1904) and Gabriel García Márquez (b. Colombia 1927) who combine elements of indigenous and Catholic religious ideals and myths with everyday life serves as a vehicle for exploring questions about modern realities including scientific empiricism and the legacy of Spanish colonialism (and our perceptions of them) in a technique that has been called "magic realism" by many critics. The contemporary Spanish author, Juan Goytisolo (b. 1931), has explored in his novels how modern Spanish culture is defined in part by its denial of its own Muslim and Jewish pasts. Goytisolo recurrently uses the Arab and Jewish legacies of Iberia as background for his fiction, which delves into alternative sexualities and identities. Historical novels, many of which unfold in the multireligious and multilinguistic atmosphere of medieval and Renaissance Spain have become bestsellers in the first decade of the twenty-first century.

Sources of Authority

For the study of language use and literature of earlier periods manuscripts and early printed documents are the chief authoritative sources.

For more recent literary production in the twentieth and twenty-first centuries, recorded (television, radio) interviews with authors, as well as the peer-reviewed studies of prominent literary scholars are considered authoritative texts, in addition to the author's own literary works. For linguists documents and recorded interviews with speakers of the language or dialect to be studied, in addition to the peer-reviewed studies of leading experts in the field provide authoritative information.

Ethical Principles

While today scholars of Spanish language and culture generally do not identify their work as being religious in nature, the Catholic, Jewish, and Muslim past and cultures of Spain are often a topic of Spanish literary works, and consequently of the studies of them. Increasingly the study of languages, cultures, and literatures of the Spanish-speaking world has been driven by an ethical evaluation of the areas' colonial past. Representation is a central focus of most work being done by literary scholars, and to a lesser, but not insignificant degree by linguists. Contemporary scholars are also looking to the other languages and literatures of the Spanish past – the Hebrew, Arabic, other Romance dialects, Nahuatl and Quechua, among many others, to explore the ways in which Spanish language and culture has contributed to the creation of new, hybrid cultures. This focus entails not only a reevaluation of the cultural production of the Americas, but of the other dialects and literatures produced in the languages of the Iberian Peninsula such as Catalan, Basque, and Galician-Portuguese, and more recently those of the North African and Latin American immigrants. Investigations into the dialects of Latin America have revealed much about creole and pidgin languages, and about the hitherto unrecognized influence of African languages and religious beliefs in the dialects of the Caribbean. Scholars of Spanish literature and culture are currently investigating how postmodern theories about memory, colonialism, and

trauma can be applied to the literature of the Spanish past. The colonial legacy and the complex histories of cultural engagement with many different linguistic, confessional, and regional groups gives Spanish language and culture much to offer newer theoretical approaches to Diaspora, Translation, and Globalization or Transnationalism.

Key Values

Values of this discipline change over time and place.

Conceptualization

Nature/World

Historically, nature was considered by Spanish Aristotelians such as Ibn Rushd as being the material, observable world. In the eighteenth and nineteenth centuries, nature became a construction used to reflect the emotions of authors of the Romantic period, or conversely a hostile force that represented all that was not human and that stood in contradistinction to the values humans cherish most, such as civilization, knowledge, and compassion. There is a growing ecological movement in Spain in which writers and artists have major roles.

Human Being

In the Middle Ages, the human being was considered by many Spanish thinkers as material, worldly matter (the body) combined with a small part of the essence of the eternal or divine (the soul). The tension between these two constitutive parts was thought to give rise to the emotional and physical characteristics of the individual human being. For contemporary linguists the human being is defined and distinguished by language use. Much contemporary literature in the Spanish-speaking world is concerned with the human being as a being privileged over others with certain rights, such as freedom from torture and brutality, and as a witness to larger historical processes or events.

Life and Death

These concepts differ according to the personal beliefs of each author and scholar. The nature and meaning of both has found representation in a number of Spanish literary works across centuries and these reflect not only the beliefs of the author, but also the currently held notions of the time period during which they write.

Reality

Authors writing in Spanish have long questioned the limits of reality. In earlier periods, reality included both this world and the metaphysical realms associated with God – the heavens, eternity, etc. Twentieth-century authors in both Latin America and Spain have explored alternative realities beyond the observable physical world. These alternatives include other possible but unrealized futures or pasts, psychological states, and the supernatural. For authors and critics of postmodernism, reality is mediated and constructed by language (see “[Truth](#)” below).

Knowledge

For many medieval Spanish thinkers knowledge was a universal and quantifiable object, that which could be known. For many thinkers knowledge could be attained by the individual both by observing the material world and through religious texts such as the Torah, Quran, and Christian Bible. For more contemporary authors in the Spanish-speaking world, knowledge is a political category often used during imperial or colonial expansion to justify the exclusion of certain groups from the power structures that both defined and controlled the production of knowledge.

Truth

For many contemporary authors and scholars of Spanish literature truth, much like knowledge, is a constructed and ultimately mutable category determined in large part by the historical moment, geographical space, and personal circumstances of its enunciation. Many linguists and literary critics would consider truth and truth claims as both constructed and determined by language.

Perception

For many thinkers, perception would be the way an individual experiences and interprets the world around him/her. Many authors have used fiction to question the limits of human beings' modes of perception. For many linguists, authors, and critics, perception, much like reality and truth, is wholly determined and mediated by language.

Time

A manner of structuring events in a linear fashion. Some recent authors, most notably Jorge Luis Borges, have examined the relativity of time as experienced by humans.

Consciousness

What humans experience in their waking state. This condition has been explored and problematized in the work of the sixteenth-century author Pedro Calderón de la Barca and in that of the twentieth-century authors Alejo Carpentier and Jorge Luis Borges (among many others).

Rationality/Reason

Categories of central importance for Spanish authors of the Middle Ages. For many Spanish thinkers such as Ibn Rushd and Maimonides, rationalism and reason were of Aristotelian origins and described the way of thinking or structuring knowledge according to which men could observe the processes and behaviors of the natural world and from those observations predict the behavior of future events, objects, and similar processes. For these thinkers observations and rational conclusions based on them would assist men in learning the way in which God had structured the cosmos. In the twentieth and twenty-first centuries authors of Spanish-language literature have used fiction to question the assumed empiricism of reason and its role in the Spanish colonial enterprise.

Mystery

A term used to describe the unknowable, which for many authors, critics, and linguists would be that which is beyond language and therefore

beyond thought, perception, time, etc. The Spanish literary tradition includes many mystics, such as the sixteenth-century San Juan de la Cruz and Santa Teresa, who attempted to describe the unknowable through poetry. In the Middle Ages Spain was also home to many Jewish mystics, or kabbalists, who penned works in Hebrew.

[African languages and literature](#)

Description

Though, studies in languages and literatures of Africa may be approached independently, but the strong connection between the two in providing holistic understanding of the African worldview has made an inclusive engagement of the two disciplines not only fashionable but also productive. The study of African languages (means of communication of cultures and symbols) addresses issues such as the number of spoken languages and their groupings. Overall, there are about 2,028 languages in Africa, representing

about one third of languages spoken worldwide, on the other hand African literature (the verbal or written forms through which the truths of different cultural dynamics are communicated) is located in the combination of oral and written literature. The contemporary written African literatures done both in local and foreign languages are largely historically indebted to transitional dynamics of oral literature built on genres of prose, tales, epics, and poetry of different forms (Beier 1967).

Self-identification

Science

While languages and literatures of Africa may not be regarded as “physical science,” however, they do come under the orbit of “social sciences,” inasmuch as they become subjects of scientific investigations, development of hypothesis, and empirical testing in discovering and predicting the African use of language in describing nature as well as literary dynamics involved in depicting the diversity of African cultures and description of the natural and social phenomena in shaping the African identity.

Religion

Though languages and literature cannot be strictly identified as a religion, they are significantly linked with it. From the perspective of language, religious beliefs and practices are language-based. Also, there exist “religious languages” which are coded formulations of specific religions. For example, African languages are central to indigenous African religion. They depict the diverse but unique religious beliefs of Africans through multilingual formats. African literature, both oral and written, has been significantly linked with religious genres. Indeed, African oral literature is basically expressions of religious ideals located in traditional myths rendered via prose, narratives, and poetic formats. In the same vein, contemporary African written literature, while not limiting its scope to only religious themes, has drawn largely from both indigenous and foreign religious backgrounds practiced by Africans in its fiction, poetry,

and theater outputs. For example, the work of Fagunwa (“The Forest of a Thousand Daemons”), written in the Yoruba language, depicts the mythological worldview of the Yoruba people with an undertone of the influence of the Christian God. In the English language, Wole Soyinka’s “Death of King’s Horseman” was based on Yoruba metaphysical belief of the afterlife. Also, Chinua Achebe’s novel, “Things Fall Apart,” characterized the tragedy represented by the arrival of Christianity and colonialism for the Ibo people of Eastern Nigeria.

Characteristics

African languages and literature, whether as independent disciplines or taken as one, are very distinctive and central to all other disciplines/studies about Africa. There is no doubt that the languages spoken by a group of people constitute the bedrock of their self-identity. In the same way, both oral and written literatures of any community usually provide the watershed for the understanding of their holistic ways of life. For the African people, languages and literature, both indigenous and acquired, have and continue to distinctively provide for all other forms of disciplines associated with Africa – the understanding and appreciation of the diverse, rich, and unique life experiences and responses of the African people.

Relevance to Science and Religion

The disciplines of languages and literatures of Africa are not only compatible with the scholarly study of “science and religion”; they, in fact, constitute the very dynamics of any meaningful engagement in science and religion with the African people by ways of expressions in languages and oral and written reflections in literature.

Sources of Authority

For languages in Africa, the pioneering work of identifying and classifying African languages

was undertaken by Joseph Greenberg (1970). He classified the languages of Africa into four categories, namely, (1) Niger-Congo (150 of about 360–400 million speakers), (2) Afro-Asiatic (300–500), (3) Khoisan (35–50), and (4) Nilo-Saharan (190–250). Further work was done by Mazrui and Mazrui (1998), whereby languages of Africa were classified into (1) Afro-ethnic, (2) Afro-Islamic, (3) Western, and (4) Afro-Western.

Today, the study of African languages and literature has become a very significant part of the academic program in Africa, Europe, and America. Universities located all over these continents have thriving Departments of African Languages and comparative literatures with extensive researches and publications on African languages and literature. Some African languages which have gained international recognition and taught in many world universities are Swahili, Yoruba, and Hausa.

Also, African literature in oral and written forms, both in the indigenous and foreign languages of Africa, has become a significant area of academic pursuit in universities all over the world. For example, works in languages such as Sesato, Ahosa, Zulu, and Yoruba, even though under the shadow of efforts associated with the translation of the Bible, have been able to weather the tension of competing Christian and indigenous African beliefs. Indeed, the importance of African literature in African languages has been stressed by many African writers as a form of intellectual protest against colonialism and imposition of foreign languages. Kenyan writer Ngũgĩ Wa Thiong'o vividly represents this position by insisting that "it is only revitalized African languages that will be best placed to give and receive from the wealth of our common (African world) culture on an equal basis" (Ngũgĩ 1990, p. 981).

African literature written in foreign languages is largely dominated by Anglophone and Francophone colonial experiences. According to Gordon and Gordon (2007), this form of literature emerged to serve dual challenges: (1) the African literary response to accounts about Africa and (2) addressing problems of African nations.

Within these contexts, authoritative African writes are found in diverse areas of literature such as fiction, poetry, and drama. African literature written in English is most prominent in Anglophone regions of West, East, and Southern Africa. In West Africa, Nigerian writers are best known and most prolific in literary works in forms of novels, poems, and plays. The impetus for these writers is traceable to two traditions – "Onitsha Novels" (market where these novels were sold) and the university College of Ibadan founded in 1948 (Gordon and Gordon 2007). The early best-known novelists in Nigeria include Cyprian Ekwensi with many popular novels including *"Peoples of the City"* (1954) and *"Jagua Nana"* (1961). Chinua Achebe also wrote many popular novels, among which are *"Things Fall Apart"* (1958) and *"Arrow of God"* (1964). In the poetry category, figures such as Christopher Okigbo and John Pepper Clark are very prominent. Perhaps the most celebrated Nigerian novelist and playwright is Wole Soyinka, the first African to win the Nobel Prize in Literature. He has numerous novels, poems, and plays to his credit, some of which are *"The Interpreters"* (1965), *"Ake: The Years of Childhood"* (1981), *"The Trial of Brother Jero"* (1963), and *"Opera Wonyosi"* (1981). The second generation of West African writers of novels, poetry, and drama includes prominent names such as Odia Ofeimun, Kole Omotosho, Ola Rotimi, Tess Onwueme, and Tanure Ojaide. From East Africa, literary authorities in English include Kenyan Gaze Ogeit and Ngũgĩ Wa Thiong'o, Ugandan Okot P Bitek, and Somalian Andrew Guor. The Southern African region has produced literary authorities in John Eppe, Tisiti Dangaremba, and Yvonne Vera, all from Zimbabwe. In South Africa, African literature has been able to survive the apartheid years with the attempted imposition of the African language and the forcing of writers such as Dennis Brutus and Alex La Guma into exile. Those who remained behind like Sipho Sepamla and Manaka Mitsemala, despite censorship, have been able to lay some credible foundation for the emergence of postapartheid writers of African literature in English, such as John Maxwell Spetzen,

Gordimer and Coetzee (both Nobel Prizes winners), Rayda Jacobs, and Zakes Mda.

The Francophone regions of Africa have also contributed authoritatively to African literature in forms of novels, poems, and plays written in French. Some prominent writers here include Yambo Ouologuem, (*La Devoir de Violence* 1966), d'Ahmadou Kourouna (*Soleils des Indépendences* 1968), and the female writer Aminata Maiga (*La Voie du Salut* and *Le Miroir de la Vie* 1985).

Ethical Principles

African languages have traditionally been guided by moral standard, which enforces the avoidance of foul and negative thoughts and words while promoting positive ones as beneficial for good character building. Africans ascribe potent and efficacious dynamics to words uttered through language. For example, the Yoruba people of Nigeria substantiate this notion in a saying that “as words could bring cola-nuts from the pocket so could words also lead to drawing of swords.” Also, African literature, both oral and written, has largely been devoted to the ethical and moral philosophy of the African people. Thus, mythical narratives of African oral literature are celebrating traditional moral values of respect, humility, honesty, kindness, hospitality, and dedication while denouncing of vices such as sexual transgressions, murder, stealing, lies, and property covetousness. Also, written African literature either in local or foreign languages has maintained this tradition, though with contemporary tendencies. Contemporary African literature (novels, poems, and plays) has taken the burden of addressing ethical issues, such as justice, freedom, and equality, both in pre- and postindependent African nations.

Key Values

Pursuits in African languages and literature have become very valuable and have been demonstrated, first, in the engagements of identifying

and classifying existing African languages and their usages with the efforts of saving them from the threat of extinction posed by foreign languages, especially English and French. Second, African literature in its different forms has become the sustainability agent of African cultural beliefs both in the traditional settings and in their contemporary comparative and competitive dynamics as distinctive worldviews. Thus, studies in African languages and literature have become valuable vestals of the African unique, yet diverse, self-identity in cultural, religious, political, social, and other human engagements.

Conceptualization

Nature/World

Through African languages and literature, nature is regarded as being holistically significant both materially and spiritually. While nature may be material in composition, its origin and sustenance are divinely driven.

Life and Death

There is the subscription to the divine creative origin and process of life. Man as a living being is made of material body and spiritual soul. Death does take place, but it is restricted to the material body, while the soul lives on. Ultimately, death is regarded as transitional process rather the end of human life (See Beier 1966).

Reality

The languages and literature of Africa depict beliefs in reality made up of both physical and spiritual components. The human reality is projected as containing both positive and negative experiences. The Supreme Being is real, and the religious and moral propensities of relationship with Him here on earth are determinants of a life after in the supernatural domain, concepted as real as the physical world.

Knowledge

Knowledge has always been valued by Africans. Thus, wisdom, regarded as synonymous

with knowledge, is not only expressed through the media of African languages but almost exclusively constitutes the themes of African literary works in novels, poetry, and drama. These have become custodians and instruments of dispensing various aspects of knowledge – ritual practices, morals, natural science, and physical as well as metaphysical beliefs.

Truth

African languages and literature understand and celebrate the existence and value of truth as epitome of human life. Truth is regarded as central to human good and integrity. This is at both individual and societal levels. Its presence guarantees not only social and earthly favors but divine ones as well.

Perception

The belief that human perception of the material and spiritual phenomena are interconnected is vividly reflected through expression in African languages and captured in various ways by African literary works in whatever languages they are written.

Time

Traditionally, African languages and literature (oral) identified time with space. Thus, time was important as of geographical (0) and immediate experience. However, with the influence of Western languages (spoken) and African literature, the concept of time in futuristic dimensions has become fashionable.

Consciousness

Human consciousnesses of both the physical and the spiritual phenomena are well located in different African languages and have been popular materials for both oral and written African literature. This consciousness encompasses the knowledge of the physical phenomena derived from the five senses and the spiritual ones derived through extrasensual awareness of rituals, dreams, visions, and other metaphysical experiences.

Rationality/Reason

The African search for understanding of human life and purpose is concretized in rational processes expressed and narrated in oral and written literature. The diverse languages and different forms of literature attempt to give meaning to both the physical and the metaphysical domains of African existence.

Mystery

African languages and literature depict the reality of a realm of existence and awareness beyond the here-and-now human consciousness. They portray an interconnection of the two that may be beyond mundane understanding – wrapped up in a world of mystery.

Lateral Inhibition

Jörg-Peter Ewert

Faculty of Natural Sciences, University of Kassel, Schauenburg, Germany

Lateral inhibition increases the sharpness of contrast in sensory responses, for example, to a contrast border in vision. It refers to a sensory neuronal network arranged in at least two layers of arrays of neurons connected by excitatory and inhibitory inputs. Suppose an array of excitatory visual input to layer-1 in the manner of a contrast border:

Excitation in layer-1: 8 8 8 8 8 8 **8** 4 4 4 4 4 4

The neurons of layer-1 will now excite via their axons the corresponding neurons of the subsequent layer-2. Via axonal branches of those axons, the laterally adjacent neurons in layer-2 are inhibited by a percentage of the excitation. Upon passing lateral inhibition (say 25% of excitation):

Excitation in layer-2: 4 4 4 4 4 4 **5** 1 2 2 2 2 2

Thus, lateral inhibition attenuates the overall excitatory input and sharpens the perceived contrast border.

Latina/Latino Studies: The Borderlands

The study of people of Latin America descent in the United States, or "Latina/Latino Studies,"

began as part of the current of demographic and political changes in the 1960s. While college and university departments had long studied Latin American history, society, and culture, there was a dearth in the literature on the generations of Latin Americans in the United States, now numbering some 40 million. As Latinas/Latinos increasingly enrolled in institutions of American higher education, they like African Americans and feminists, demanded courses that were relevant to their own experiences. Thus, new academic departments began sprouting up first in California and then across the Southwest and into the East. Today there are dozens of both Chicana and Chicano (Mexican American) and Latina/Latino study departments across the nation. The following entry relates the topic of Latina/Latino studies to the themes of religion and science by focusing on the ways Latina/Latino studies theorize academically Latina/Latino religions: the borderland thesis. In what follows I look first at Latina/Latino history and then to the borderland theory all with an eye toward religious expression in the last half of the entry.

Colonialism: Mestizaje

The story of contemporary religion for Latina/Latino across the United States-Latin American borders, the *borderlands*, begins with Spanish colonialism. In 1421 the *Mexica* or Aztec Mesoamerican imperial capital, Tenochtitlan, fell to an army headed by invading Iberian Christians; in 1533 the Inca Empire of South America lost its imperial capital, Cuzco, to the same fate. These victories heralded a new colonial order throughout what is now Latin America, from the Tijuana border, to the southern tip of Argentina, to the former Spanish colonial islands of Cuba, Puerto Rico, and the Dominican Republic. In the nineteenth century, Latin American colonies liberated themselves from Spanish rule and became hybrid republics, torn between their indigenous, European, and African underpinnings. For the most part, Latin American statecraft came to manage the resulting inevitable process of cultural

blending and synthesis by recognizing and celebrating its creative potential and effects, rather than complete condemnation of its perceived impurities.

In one sense, “the borderlands” name the place and result of this history – a hybrid social and geographical space, a result of imperial Christian impulses and stubborn Indian resistances, emergent in a repertoire of performances that continue to morph. This evolutionary phenomenon is in no way unique to Latinas/Latinos; indeed, it happens in all human societies. Yet, the historical and geographical contexts, the places and facts of cultural contact, are in fact dissimilar and contribute to a particular regional matrix of variations, local culture – borderland culture. And indeed, traditions develop that possess the aura of always having existed so that multitudes invest great meaning in them – they become important enough to ground personal and national master identities.

Still Nepantla

For the ancient Mexican Nahuatl speakers, the place of tradition was known as *nepantla*: the space in-between worlds. Colonial Christians were bewildered by the wonders they encountered in the fifteenth-century Mesoamerica. When one Indian wise man was asked why he continued practicing his religious traditions after having formally received Christian confirmation, his answer was prophetic. “Don’t worry father,” he reassured, “we are still *nepantla*.” The place of in-between, occupying the porous borders at once connecting and separating Maya from Aztec, Taino from African, indigenous from Spanish, Christian from pagan, and, ultimately, Latina American from the United States.

Even after colonization, the colonized peoples across the American borderlands never entirely surrendered control of their bodies, memories, and sacred places; their control remained partially in the realm of the spiritual. Religions are shaped and reshaped in the struggle for political power. Classical social theorist Emile

Durkheim once correctly noted that human nature does not explain religious phenomena; instead we must look to their social contexts for explanations.

Borderland Religions

Embedded in the trajectory of Chicano history, the borderland thesis suggests that, for many Mexican Americans, cultural production occurs betwixt and between Mexico and the United States and is thus characterized by liminality, or the processual state of in-between-ness, of becoming. The organizing principle of the borderland thesis focuses on how the international boundary between Mexico and the United States, as well as adjacent regions, creates a distinctive cultural space that paradoxically links yet divides people on either side of the border. The borderlands are not only a physical place but also a poetic device for describing perennially emergent and multiplex individual, social, and cultural formations.

The grand symbol of the border looms large in the Mexican imaginary, and the reality of its daily transgression by people who may be otherwise religious and law abiding is cause for deep reflection. Mexicans who come to the United States put their faith in the “cross,” the act itself that becomes a symbol. Metaphorically, a border-crossing consciousness means living daily with the impulse to surpass institutional, religious, legal, spatial, and symbolic barriers that keep the colonized, those on the margins, away from centers of power. Borders of all kinds are central and formative places in the production of religion, but they also serve as peripheries that must be surpassed to arrive at a place with greater promise – a meaningful and better orientation for cultural and religious migrants.

The incessant illegal crossing of Mexicans into the United States should give us pause. Each year millions of Mexicans are arrested for crossing the border. Others attempting to cross the border suffer a worse fate: each year hundreds of bodies are found in the desert between Mexico and the United States. The ocean separating the Caribbean Islands

from Florida functions as a watery burial ground for thousands of people each year who attempt to cross over from Cuba, Haiti, and the Dominican Republic. Various forms of religion provide hope and strength for these often destitute border crossers, pilgrims in a sense, on their faith journeys to the promise land.

Borderland Religious Expression: Response to Crisis

Contemporary religious expression among people of Latin American origin, Latinas/Latinos, on both sides of the United States-Latin America border – the *borderlands* – is a product of many historical collisions and social collusions. The myths and realities of Spanish colonialism interfaced and merged tensely with the indigenous Americas. In the Caribbean and on the eastern coast of South America, this religious matrix combined with the myths and realities of indigenous African traditions brought to Latin American shores by slavery to produce the radically innovative hybrid religions among existing today. Borderland religion owes its origins to at least three main sources of religious tradition and innovation: indigenous Americans (chiefly Maya, Inca, and Aztec), primitive form of Spanish Catholicism which ironically resembled the beliefs and expressions it sought to eradicate, and west African Yoruba rites and practices.

Still, however, indigenous traditions survived in processes of subterfuge, dissimulation, and outright defiance. The phrase “idols behind altars” has been used to capture the ways that the indigenous peoples of Latin America rejected the singularity of Christianity even well after formal indoctrination was imposed. In Cuba and throughout the Caribbean African, slaves were imported en masse to fill the labor void left by the largely decimated indigenous Taino populations; many Indian survivors fled to mountainous island interiors which soon attracted escaping African slaves and thus became productive venues of religious experimentation – producing fresh indigenous-Catholic African hybrids, Santería chief among them.

In African diaspora religious formations the “crossroads” mark the meeting place of the living and the dead, wherein spirits cross the border between life and death. Crossings symbolize action, movement, and transformation: the “cross” is a verb. Pilgrims carry and enact the cross from South to North America, from the Third World to the First, from certain poverty to uncertain poverty, from the old to the new, refiguring multiple covenants of grace and hope. The cross bears several meanings but becomes most significant in Latina/Latino religious practice as both noun and verb. Migrants intersecting the northern border reenact a drama of religious transformation that is centuries old, at least: a life translation. Conversion, new life, transformation, and renewal of spirit are realized in the intersections created by the cross.

Latina/Latino immigrants typically follow the seasonal patterns of crops and other labor rhythms (e.g., the demand for construction workers being greater during the non-rainy months). And inasmuch as migrants touch and inform the lives of permanent residents in the spaces they inhabit, entire communities are affected by cycles of return: various communities and social collectives experience ebb and swell as a function of migration. For a community delimited by border crossing, fluidity, and movement, religion is experienced as flux and flow; the greatest religious movements occur at times of crisis.

When people come to the United States, they bring their religious traditions with them; when they come as temporary workers, they return to Mexico with the commodities and cultural influences they accumulated while in exile – both are disseminated in their homelands. Thus, the cultural rhythms of the United States pulsate into Mexican religious systems, and vice versa, in various means of transnational exchanges. Both nations are influenced by the transnational movement of peoples – bodies and souls – a cycle that takes place again and again.

The borderlands are crossroads, functioning at once as symbol and reality for millions of Latinas/Latinos who cross boundaries of many kinds when forging plausible and effective

realities for themselves and their posterity. The cross as metaphor can be effectively used to connote Latina/Latino religious practice insofar as borders isolating traditions from one another are diminished while practitioners draw from many spiritual resources in their struggles to survive the oppressive legacy of colonialism.

[Memory](#)

Description

The study of learning, and its outcome – memory, involves the effort to identify how we acquire internal representations of experience, how these representations are stored, and how they are expressed in thoughts, feelings, and actions. The scientific study of learning and memory study evolved separately in major academic disciplines of psychology, biology, and clinical medicine. Psychologists have most prominently focused on rigorously designed experimental studies that have generated a large body of information about how information is encoded, remembered, and forgotten. Psychological research on animal memory focused on discovering universal rules of learning in distinctive training protocols, including classical conditioning and instrumental conditioning. Psychological research on human memory has revealed an organization of the structure of memory, different stages of learning and memory, including

short-term memory, working memory, long-term memory, and distinct forms of memory, including declarative memory and procedural memory. Biologists studying the brain have focused on anatomical and physiological correlates of learning and memory, revealing how networks of brain cells are changed as a result of learning. These studies have shown that learning is most prominently associated with changes in how neurons communicate with one another at their ► [synapses](#). Clinical medicine has discovered cases of ► [amnesia](#) that shown how memory is compromised as a result of brain injury or disease, revealing much about the organization of normal memory, and has revealed that learning and memory are distinct from other mental capacities such as perception, feeling, and action. Among the most prominent recent developments in this specialty is a convergence of understanding gained by combining the discoveries from these distinct disciplines, particularly with the new discipline of ► [cognitive neuroscience](#). The main new discoveries are that there are multiple types of memory, that these types of memory are supported by distinct brain systems, that the same systems exist in animals and humans, and that the fundamental basis of learning and memory involves the organization of knowledge through changes in neuronal connections via molecular mechanisms that are common across systems and species. For further details on this issue, and on the succeeding questions, the reader is referred to recent texts on the topic of learning and memory (Schacter 2001; Eichenbaum 2011).

Self-Identification

The study of learning and memory has a rich history in philosophy and the nature of memory is a topic of examination by writers and thinkers in many disciplines, including both literary (e.g., novelists) and technical (e.g., computer scientists) perspectives. However, most of the traditional study of memory is a science because it is pursued by the scientific method in which observations are made, hypotheses about the mechanisms underlying those observations are

formed, experimental tests of those hypotheses are made, the results modify or elaborate hypotheses that are tested by further experiments, and so on. These studies have generated many theories of learning, including that learning involves record of perceptual experience; that learning involves associations between stimuli, between a stimulus and a reward or punishment, or between a stimulus and a behavioral response; or that learning involves the networking of knowledge about the world. Scientific studies at various levels of analysis, from behavior to ► [brain imaging](#), to the analysis of localized brain damage, and to the physiology and molecular biology of single neurons and synapses, have distinct traditions in what constitutes a hypothesis and in the nature of experiments used to test these hypotheses.

Characteristics

Our individuality is the product of a lifetime of learning. We are genetically programmed to babble, but we learn to speak a particular language with a personal vocabulary and a library of facts and concepts that is special to our culture, and we learn our personal autobiography. Learning is also unique because it is pervasive in our everyday life and should be viewed as a feature of plasticity and malleability in all of the ways by which we improve our skills, change our dispositions, and add to our knowledge about the world and personal experiences.

Relevance to Science and Religion

The science of learning interfaces with many aspects of education within society. The principles and processes involved in learning apply to the training of humans and animals at home and at work; to classroom education; to behavioral therapies for mental disorders including anxiety, addiction, and much more; and to the loss of learning ability in aging and disease. Religion may be thought of as a specific organization of knowledge derived from learning.

Sources of Authority

The primary sources of authority in this specialty are the record of scientific analyses typically published in journals and other print or electronic media or oral lectures. The most authoritative sources involve journal articles that are reviewed by peer scientists who judge the rationale of the studies and the scientific methods of experiments that test hypotheses against accumulated knowledge in the specialty.

Ethical Principles

The ethical principles that guide this specialty are honesty in the presentation of experimental findings and evenhandedness in the interpretation of the data as they relate to different hypotheses.

Key Values

The key value in this specialty is a deeper understanding of the underlying principles and mechanisms by which learning occurs and determines the organization of the resulting memories.

Conceptualization

Nature/World

The world is defined as the composite of stimuli, events, and their contingencies in which learning drives our adaptation to the structure of the environment.

Human Being

Humans likely have more elaborated learning capacities than other animals, but the fundamental principles of learning and types of consequent memory are shared with animals. Each individual human being is defined as unique by a lifetime of learning.

Life and Death

Life is adaptive, and adaptation to the world involves a combination of evolutionary

adaptations that are governed by our genetics and learning about the world in order to interpret and make predictions about specific future events.

Reality

Within this specialty, reality is what we learn from experience. Any other realities, such as supernatural forces, exert their independent existence by altering the experiences that are learned or, alternatively, exist in terms of an organizing principle of knowledge that is learned.

Knowledge

A major purpose of learning is the acquisition of knowledge from experiences. Within the science of learning, knowledge can be viewed as the organization of the record of experiences that can be retrieved through remembering.

Truth

The truth of knowledge acquired from learning can be tested in terms of consistency with other records of past events and in predicting future events. Within this scientific specialty, truth may also be viewed as a fundamental principle or framework for the organization of knowledge about the world.

Perception

Perception is not a passive witnessing of events but instead involves highly active and directed efforts at analysis of events. Moreover, what we perceive depends greatly on our expectations derived from prior learning as a consequence of experiences with similar stimuli and events.

Time

Time involves the order of events that occur in experience and is a fundamental feature of what is learned and incorporated into some types of memory. In particular, episodic memory is viewed as a record of time. In semantic memory, the factor of time is eliminated.

Consciousness

Memories can be conscious or unconscious, and conscious awareness reflects the operations of

different learning systems. Declarative memory is defined in terms of our ability to bring what has been learned to consciousness. Conversely, nondeclarative memory is defined as learning that occurs and can be expressed without conscious awareness of specific learning events. Some have defined consciousness as the product of declarative memory by which we experience conscious recollection when we recover the context and associations of prior experience with a memory cue.

Rationality/Reason

Rationale thought and reason can be thought of as a property of the knowledge acquired through learning. In prototypical terms, we have many learning experiences in which the acquired associations overlap and the resulting network of knowledge allows us to reason. For example, we might learn that Sally is married to Joe and, on a later occasion, learn that Sue is Joe's sister. Each of these learning events is represented within our framework of knowledge acquired from additional learning about familiar relationships. Next time we see Sally, we can reason about her association with Sue and ask about her sister-in-law. Within the science of learning, the same principles apply in religious reasoning, with a framework of knowledge specific to religious training.

Mystery

Within the science of learning, mystery is our failure to fit a perceived event into the framework of our acquired knowledge. A mystery is resolved when we can link the event to others by modifying or elaborating the structure of the knowledge framework.

Relevant Themes

Belief and learning reflect distinct ends of the spectrum of our interpretation of the world. Belief may be viewed as a closed framework of knowledge in which succeeding events are interpreted as consistent with a fixed framework,

such that fundamental abstractions (“truths”) are sufficiently vague as to incorporate any new experience. The science of learning, by contrast, highlights that the framework of our knowledge is continuously subject to change as a result of new experiences and that truth is an ever-changing abstraction of the sum of our experiences.

Description

The term “Liberal Theology” denotes various philosophically, theologically, and biblically informed religious movements and ideas that emerged within Christianity during the so-called Age of Enlightenment in the eighteenth century. These movements and ideas can in large part be seen as reactions to Enlightenment philosophy and rationalism.

There are two major strands of Liberal Theology that developed out of the reception of the philosophies of either Immanuel Kant or Georg W. F. Hegel. Liberal Theology sprang from the minds of the thinkers that still held fast to Christian belief even though this belief was attacked by the key developments of the Age of Enlightenment. It developed within the church and it tried to salvage Christianity by surrendering those ideas, assertions, and features that were no longer seen as justified and well-grounded in the modern world. Liberal theological tradition in fact paved way for a new religion which retained old terminology, but radically redefined those terms in the spirit of and in some part against certain elements of Enlightenment rationality to give them new meanings. The aim of these redefinitions was not to overthrow historic Christianity, but to salvage the central meanings of Christianity from the direct attacks of rationalism based on unbelief.

The Enlightenment gave birth to ideas that we still see today as part of the modern mind.

In theological terms, it might be argued that man during the Enlightenment saw it as possible to philosophically reason his way to God (cf. Neology). The key features of Enlightenment thought include at least the following: the beginning of scientific history, that truth must justify itself before the bar of reason, that nature is the primary source for answers to the fundamental questions of human existence, that freedom is necessary to advance progress and human welfare, that literary and historical criticism are necessary to determine the legitimacy of our historical legacy, the necessity of critical philosophy and ethics as separate and independent of the authority of religion and theology, a suspicion of and hostility to all truths claiming to be grounded in an authority other than reason (e.g., tradition or divine revelation), that it is through science that man comes to find truth, toleration as the highest value in matters of religion, and a self-conscious continuation and expansion of the humanism first developed during the Renaissance.

The beginning of Liberal Theology was Friedrich Daniel Ernst Schleiermacher (1768–1834). Schleiermacher was born into the intellectual climate of the Enlightenment and Kant's critical philosophy. The young Schleiermacher accepted the Neologians' criticism of Lutheran orthodoxy (the doctrines of the Trinity and the two natures of Jesus), but rejected their rationalistic and moralistic substitute. Around this time, Schleiermacher was drawn into the Romantic Movement which was developed in reaction to the sterile critical and analytical rationalism of the eighteenth century. Romanticism stressed the intuitive and synthetic nature of human reason, insisting that truth was to be gained by grasping the whole rather than by an abstract analysis of the parts. Romantic philosophy also led to a curiosity about and appreciation of other peoples' religions as authentic ways of expressing the human experience.

Schleiermacher's theological program, which he developed under the influence of romanticism and Immanuel Kant's philosophy, proceeded from three premises: (1) The validity of the Enlightenment criticism of dogmatic Protestant

Orthodoxy. (2) Romantic Idealistic philosophy gives a better foundation on which to ground the Christian faith than the shallow moralistic rationalism of the Enlightenment. (3) Christian theology can be interpreted in terms of Romantic Idealism and thus allow mankind to be both Christian and modern while being intellectually honest. From these three premises, it further develops two central arguments concerning religion and piety: (1) The piety which forms the basis of all ecclesiastical communions is, considered purely in itself, neither a knowing or a Doing, but a modification of feeling, or of immediate self-consciousness. (2) The common element in all howsoever diverse expressions of piety, by which these are distinguished from all other feelings (or, in other words, the self-identical essence of piety), is this: the consciousness of being absolutely dependent, or of being in relation with God.

Schleiermacher, by taking into consideration Kant's critique of pure knowledge which he saw as a destruction of the possibility of a rational knowledge of God, found a new starting point for religion and theology. This seat was not influenced by the Enlightenment critique. The feeling (*das Gefühl*), which is not to be understood as a mere emotion, opened up the view of a deep inner sense of man that he exists in a relationship of absolute dependence upon God. This god-consciousness was taken to be the center of religion.

Thus, Schleiermacher turned the traditional theological method upside down. Rather than starting with any consideration of objective revelation, religion was now seen as in its core subjective. Experience was seen as giving rise to doctrine rather than doctrine to experience. Theological statements were no longer perceived as describing objective reality, but rather as reflecting the way that the feeling of absolute dependence is related to God. It is this experience which is seen as the final authority in religion rather than the objective revelation of an inerrant Scripture.

Whereas Schleiermacher was in a sense a mystic, seeing the center of religion in the feeling of absolute dependence upon God,

Albrecht Ritschl (1822–1889) was more closely tied to Kant and construed religion in terms of morality and personal effort in establishing the Kingdom of God (a moral-ethical Kingdom).

Religious truth in the Ritschlian conception became different in kind from all other knowledge; it involved moral-ethical judgments which were subjectively determined by the individual. The system surrendered rational knowledge of God and things divine. In its place it substituted, as the essence of Christianity, a subjectively verified personal theism, a devotion to the Man Jesus Christ as the revealer of God and His kingdom, and a subjection to His moral-ethical principles. Religious truth was no longer to be found in objective, verifiable propositions but in the realm of the subjective experience, in “value judgments.” These “value judgments” were of a different nature than scientific knowledge. They gave no definite objective propositional knowledge, but set forth their subjective value for the individual.

Ritschlianism sought to separate religion and theology from philosophy and metaphysics. Following the Kantian tradition, the Ritschlians asserted that human knowledge was strictly limited to the world of the phenomena, a world which included the realm of verifiable history and the realm of personal experience. “Theology without metaphysics” became the watchword of the entire school. Knowledge of God, as He was in Himself, His essence and attributes fell outside the possibility of human experience. This is why no positive assertions concerning His nature could be made. Ritschl himself asserted (with Kant) that man could not know things “in themselves” but only in their phenomenological relations. Since man had no categories by which to perceive God in the world, knowledge of Him fell outside the realm of the “theoretic” (scientific/empirical). Since Ritschlianism was strictly empirical, the value of historical study was elevated as a means by which one could discover God’s revelation in history: the person of Jesus Christ.

Revelation of God and certainty in religion took place, for the Ritschlians, when one was confronted with the historic person of Jesus Christ.

The truth communicated in this revelation was not “theoretic” (scientific) but “religious.” Such a distinction divorced faith from reason. According to the Ritschlians, the two realms had to be kept entirely separate. For example, the existence of God could not be rationally demonstrated. But since man needs God, that was proof that He exists. However, nothing could be inferred concerning His nature, attributes, or His relationship to the world. One could not communicate objective truth about God from his revelation in Jesus Christ; the most one could say was that in Jesus Christ, one received the impression that God was present and active for him. Thus, religious knowledge (in the objective sense) became the common shared experience of God.

The comparative study of religions was also developed in the context of liberal theology. Romanticism and the increase of knowledge which came as a result of the colonization of the world by the Western European powers led to this new discipline. Vast amounts of new knowledge about the world and competing cultures and their native religions became available. The burgeoning science of archaeology opened the past and now allowed for the Bible to be studied against its cultural milieu in a way that had not theretofore been possible. All religions were viewed in their most basic form to lead to one truth (God) and to promote a common ethic of love for one’s neighbor.

Adolf von Harnack (1851–1930) was the greatest historian of Christianity among liberal theologians and his work set a standard of scholarship for the following century. Harnack operated totally within the framework of theological liberalism, seeing the pristine purity of the gospel as having been corrupted even within the New Testament era, transforming Christianity from the religion of Jesus to the religion about Jesus. Further corruption took place in the succeeding centuries as Christianity moved from its Jewish background and confronted the Hellenistic world. Controversies over the trinity and the two natures of the incarnate Christ hopelessly confused the Gospel message in Hellenistic philosophy. He argued that the task of the theologian was to get back to the kernel of the gospel by stripping

away the husks of Hellenism to find what was real and permanent.

Late nineteenth century America underwent profound sociological upheaval and this gave an impetus to the further development of Liberal Theology. The industrial revolution had thrust the problems of urban society upon a nation that had until then been primarily rural. As the problems of dynamic sociological social revolution manifested themselves in the slums and work houses, the individualistic gospel of revivalism had little to say to the problems that faced the urban dwellers every day. Walter Rauschenbusch (1861–1918) spent 11 years in the “Hell’s Kitchen” area of New York City ministering among the German-speaking immigrants. Here he saw poverty, injustice, and oppression. This led him to rethink the implications of the gospel and articulate “A Theology of the Social Gospel.” While Rauschenbusch was relatively conservative in his theological outlook, those who took up his mantle saw the message the gospel and the task of the church as working to end human suffering and establish social justice.

[Theology of liberation](#)

Description

Liberation theology emerged in the 1960s in Latin America as a response to the experience of economic poverty and political oppression. The theological quest for liberation took shape particularly in the Roman Catholic Church. Rooted in the praxis of the base communities, liberation theology became an influential movement within the Christian churches by confronting the sociopolitical conditions of the Third World with the Gospel of liberation and the search for radical social change. Liberation theology has been a significant political, social, ecclesial, and theological phenomenon. “Latin American liberation theology constitutes an unprecedented phenomenon in the recent history of Christian thought. For the first time in history, a theological creation of the Third World has acquired relevancy and meaning in Europe and the First World” (Tamayo 1993, 33).

There have been manifold relations between liberation theology and Europe. (1) A number of liberation theologians studied at European universities. (2) They developed their thinking not only in reaction to the Latin American situation but also to European thought which they took up

critically and creatively. (3) Europe in general and the Vatican in particular have been the center of criticism and condemnation of liberation thinking. (4) At the same time, alliances between European political theologies and Latin American liberation theologies were achieved. (5) From the beginning, there has been support and reception of liberation theological ideas and praxis by European groups and grassroots movements.

1. A considerable amount of the first generation of liberation theologians got their academic formation in Europe. The Peruvian Gustavo Gutiérrez (born 1928), who is called the founding father of liberation theology, and who in 1971 published his classic *“Teología de la liberación,”* studied in Leuven (Belgium) and Lyon (France). The Brazilian Leonardo Boff (born 1938) wrote his doctoral dissertation in Munich, and the Basque Jesuit Jon Sobrino (born 1938), who spent most of his life in El Salvador, earned his doctorate in Frankfurt. His dissertation dealt with the political theology of hope, elaborated by Jürgen Moltmann (born 1926). Those and other liberation theologians did not only take up modern European thought. At the same time, they criticized their colleagues for not making the decisive steps further. Gutiérrez maintained that for modern European theology, the bourgeois “nonbeliever” is the most important addressee and thus atheism is the significant conversation partner, whereas for liberation theology the “nonpersons,” the poor and oppressed masses, being deprived of any elementary conditions of living, are the first and foremost addressees and also the new subjects from the “underside of history.” Gutiérrez noted that the political theology of Johann Baptist Metz (born 1929) has been written “far from the revolutionary ferment of the Third World countries” and thus “cannot penetrate the situation of dependency, injustice, and exploitation in which most of mankind finds itself” (Gutiérrez 1973, 224). Sobrino saw European theology tied with the First Enlightenment, which was promoted by philosophers like Kant and directed at universal

reason, but in fact failed to respond to the sociopolitical challenges of the Second Enlightenment inaugurated by the revolutionary approach of Karl Marx.

2. European theologians who sympathized with liberation theology, especially proponents of political theology, were astonished when they were severely criticized by liberation theologians for being too academic, idealistic, and Eurocentric. They were accused of remaining in their splendid captivity in highly abstractive systems of concepts instead of joining grassroots movements and adopting materialistic methods of analyzing history and society. Furthermore, they were said not to acknowledge the fundamental differences between the center and the periphery. Conversely, European political theologians considered liberation theology as being methodologically weak and more of the kind of prophetic proclamation or testimony than of serious strong theology. Moltmann suspected liberation theology’s “theological provincialism,” accused it of uncritically adopting the theory and rhetoric of Western Marxism, and sticking more to “seminary Marxism” than to the life and pain of the Latin American people. This criticism is carried on by those who ask whether liberation theology is compatible with democratic society or whether it along with its revolutionary rhetoric opts for some kind of revolutionary populism.
3. While progressive European theologies nevertheless maintained a critical solidarity with and support of liberation theology, the unresolved conflict about its use of Marxist tools and methods of social analysis led to several interventions by the Catholic Church hierarchy. A Declaration of the Vatican’s International Theological Commission on “Human Promotion and Christian Salvation,” published in 1977, underlined the essential difference between historical human benefit and progress on the one hand and divine salvation on the other hand. At the same time, the use of Marxist methods in theology was strictly rejected by the Roman Commission.

In 1984, the Vatican's Congregation for the Doctrine of the Faith, led by Joseph Cardinal Ratzinger, issued an "Instruction on Certain Aspects of the Theology of Liberation." In this document, liberation theology was accused of adopting a rationalistic hermeneutics, of uncritically promoting Marxist ideology, of reading the Bible in a purely political sense, of turning the church for all into a class church and of reducing the Christian faith to a historical, worldly project. In 1986, the Vatican published a second "Instruction on Christian Freedom and Liberation" which emphasized the relevance of an "authentic" liberation theology and criticized that "some" theologies of liberation ignored the spiritual dimension of Christian freedom.

4. The Vatican's attacks, repressions, and the Roman attempts to split liberation theology have contributed to strengthen the links and alliances between "progressive" European and Latin American liberation theologies. Eminent European theologians like the French Dominican Marie Dominique Chenu (1895–1990) and the German Jesuit Karl Rahner (1904–1984) defended liberation theology in view of Vatican's accusations and pronounced in favor of its orthodoxy.

In the course of intensified dialogue with each other, European political and Latin American liberation theology more and more realized similarities between the two. These common traits include the interrelation of the spiritual and the political, and also the focus on the history of the victims and the memory of the suffering which Metz calls "memoria passionis." Both share an understanding of theology as a second act which follows political faith praxis and both opt for radical ecclesial and political changes stimulated by base communities and other movements from below. Following constructive conversation with one another, Moltmann insisted that both liberation and political theology are engaged in a common struggle "for life against death, for liberation against oppression" (Moltmann 1977, 17). German theologian

Dorothee Sölle (1929–2003) has moved on from political theology to a feminist theology of liberation. In the face of patriarchal religion orientated on God's power, God is to be thought of as a creative, liberating, and enabling power, to be experienced in the conflicts and new beginnings of every day. From the mystic presence of this power of relationship, women and men can resist and oppose the social conditions in which they live and under which they suffer. So they can work to change all the unjust social structures, mechanisms of compulsion and oppressive social relations which destroy the fellowship and equality that should be part of creation.

5. Liberation theology has only fragmentarily entered European academia. Although various centers of research on and dialogue with liberation theology have been established at universities in Europe, liberation theology got its main European reception in the realm of solidarity groups and social movements. It made its impact especially on Justice and Peace committees, on relief organizations and movements like the Young Christian Workers, the Christians for Socialism, or feminist groups and networks. Today, liberation theological thought and praxis is present in Europe in base communities and church renewal groups. Based on their political faith praxis, they reflect on the need and possibilities of a European theology of liberation, they read the Bible from the perspective of the marginalized and excluded, and they work for an egalitarian church "from below" and for a just and inclusive society in solidarity with the victims.

Life After Death

► Hope (Life After Death)

Life Course, life cycle, life history, life span and life stage

Duane F. Alwin
Department of Sociology, Pennsylvania State University, University Park, PA, USA

Life course means: (1) Events marking transitions and trajectories of roles extending across the life span, such as entering and leaving school, acquiring a full-time job, getting married, divorced, having children, retiring, and the like; (2) a perspective on the investigation of the

changing environment of the individual and its developmental implications; (3) an approach offering a way of linking early life experiences to later life outcomes, such as the exposure to early life risk factors and their consequences for later life health.

Life cycle means: (1) In biology, the term refers to the continuous and irreversible sequence of changes undergone by an organism from one primary form, as a gamete, to the development of the same form again. (2) In sociology, the term refers to a series of stages, across the life span, such as childhood and middle age, which are socially constructed and characterize the course of existence of an individual.

Life history means: (1) In biology, the term refers to the series of living phenomena exhibited by an organism in the course of development from inception to death. (2) In sociology, the term refers to chronology of events and activities that characterize a life.

Life span means: (1) The temporal focus of inquiry, for example, from conception to death; (2) the longevity of an individual; (3) the longest period over which the life of any organism or species may extend according to the available biological knowledge concerning it. Life span development then are the Multidimensional and multidirectional processes of growth involving both gains and losses, embedded in multilayered social and cultural contexts, involving dynamic processes of interaction of the developing organism with the social and physical environment.

A life stage is a phase in a sequence of age-graded statuses and/or roles, for example, childhood, adolescence, or old age. Finally, the life trajectory consists of sequences of roles and experiences over the life span defined by transitions or changes in statuses or life stages.

Limbic System

Jörg-Peter Ewert

Faculty of Natural Sciences, University of
Kassel, Schauenburg, Germany

The brains of tetrapod vertebrates comprise a set of evolutionary conserved structures devoted to functions that are needed for the survival of the species. These functions involve emotion (e.g., aggression), motivation (e.g., feeding, defending, escaping, and mating), drive (e.g., hunger, thirst), reward (reinforcement), and learning (long-term memory). Basic structures of the limbic complex include olfactory bulb, septum, hippocampus (ventromedial pallium in anurans), amygdala, nucleus accumbens, anterior thalamic nucleus, hypothalamus, preoptic area, and pituitary gland.

Liminality

Augustine Nwoye

School of Applied Human Sciences, University
of KwaZulu-Natal, Pietermaritzburg,
South Africa

Arnold van Gennep was the first to recognize the existence of the phenomenon liminality in the making of a person within the African cultural world. He used the construct of liminality to refer to the idea of a self in the condition of a transition between. He therefore used the concept to designate the experience of most African youth, inhabiting a world in between the state of “no longer” and that of “not yet.”

Explanation

Similar to other Indian religions, Buddhism is devoted to liberation from suffering, resulting in the achievement of “bodhi” (Sanskrit, meaning “awakening”) in all three traditions of Buddhism, Theravada Mahāyāna, and Vajrayāna.

As laid out by Siddhartha Gautama, the Noble Eightfold Path describes the way to the end of suffering, understood as a practical guideline to ethical and mental development with the goal of freeing the individual from attachments and delusions and to finally understand the transcendent truth about all things. Attaining the right view is hereby the beginning and the end of the Eightfold Path, which simply indicates understanding things as they really are. The right view is hereby not understood in the sense of “right vs. wrong,” rather it should be as “free from delusions,” which transcends mutually excluding categories. As a method for attaining this cognitive aspect of wisdom, Buddhist philosophers have developed a very unique form of logic of negations.

The Mahāyāna Buddhist philosopher Nāgārjuna (ca. 100–200 CE) is hereby considered the most influential philosopher for the development of Buddhist logic. He contributed two complementary concepts (Störig 2002):

1. Nāgārjuna was the first to express the Buddhist doctrine of two truths in complete modern form in the Kaccāyanagotta Sutta. The doctrine distinguishes two levels of truth (Sanskrit: *satya*):

- A “relative,” notionally categorizable, conventional truth (Sanskrit: *saṃvṛtisatya*)
- An “ultimate,” notionally noncategorizable, deepest, absolute truth (Sanskrit: *paramārthasatya*)

The two truths doctrine holds that truth exists in both forms and that they are coexistent (Störig 2002).

2. Nāgārjuna engaged the logic figure of Catuskoṭi (Sanskrit) or tetralemma (Greek) as an investigative and meditative approach to realizing Śūnyatā (Sanskrit, meaning “openness” or “emptiness”). The figure states four possibilities for any given “yes” or “no” problem, which can be answered in a variety of ways:

- Affirmation (“yes”)
- Negation (“no”)
- Double affirmation (both “yes and no”)
- Double negation (“neither yes nor no”)

In the so-called eight negations, Nāgārjuna applies the last position to the manifestations of life, by stating that there is:

- No cessation and no arising
- No annihilation and no permanence
- Not one and not many
- No coming and no going

By rejecting all firm standpoints, Nāgārjuna traces the ultimate truth beyond mutually exclusive categories of thought (Störig 2002). His philosophy of Mādhyamaka (Sanskrit, meaning accordingly “the middle way”) proposes therefore that things, including thoughts and emotions, are without essence (Sanskrit: *svabhāva*) and have existence only as they relate to other things. Therefore, it is neither true to say that things exist nor to say that they do not exist (Kalupahana 1986). Nāgārjuna would also therefore negate the fourth position (“neither yes nor no”) by adding that the “even not that” position represents the uncategorizable ultimate truth. Consequently, Mahāyāna philosophy and parts of the Vajrayāna tradition hereby hold that the relative truth and the ultimate truth are actually “nondifferent” when resolved into an experience of nonduality. In this regard, the famous Mahāyāna Diamond Sūtra (Sanskrit: *Vajracchedikā Prajñāpāramitā Sūtra*), for instance, comes to the paradoxical statement that “form is emptiness and emptiness is form” (Hanh 1996).

Buddhist logic, also called *Pramana* (Sanskrit: “sources of knowledge,” also “epistemology” or “logic”), was additionally influenced by Harivarman (ca. 250–350 CE), Vasubandhu (ca. 420–500 CE), his half brother Asanga, Vasubandhu’s pupil Dignāga (ca. 480–540 CE), and Dharmakīrti, who built on and reinterpreted his work at the turn of the seventh century (Anacker 2005). They all lived in a time of rigorous debate with the Hindu schools. Typical for Buddhist tradition, they rejected many of the premises of Hindu *Pramana*, especially the use of religious texts (*Agama*) as a source of valid knowledge alone. However, historically and culturally Buddhist logic is regarded as a particular development of “Indian logic,”

which dates back to the anviksiki school of logic, founded by Medhatithi Gautama (sixth century BCE). Indian logic, also encompassing Hindu logic (including Nyāya) and Jain logic, stands as one of the three original traditions of logic, alongside the Greek and Chinese logic traditions.

Buddhist Logic Compared to Other Traditions

From a contemporary transcultural and transmethodological perspective, the very general distinction between dialectic and classic/modern logic, as proposed by pioneer theoreticians like Johan Galtung (2008) or Erich Fromm (1989), provides a concise comparison of the great logic traditions.

1. Using the aforementioned example of Nāgārjuna, the dialectic logic can be understood as an epistemologically investigative approach to assume perspectives of higher truth and to transcend contradictions, which appear insurmountable from lower points of view. Among other dialectical traditions, Indian logic – particularly Buddhist logic – sets itself apart by tending to an approach that underlines the method of negation. Other dialectic logic methods tend to integrate contradicting positions into a higher perspective rather than completely negating them. These include, e.g., the Taoist philosophy and Yin Yang dialectics from Chinese tradition or Marxist approaches, German idealism (including Hegel), or Heraclites from Western tradition. Two examples are:

- Hegelian dialectic comprises three dialectical stages of development: a “thesis,” giving rise to its reaction (abstract); an “antithesis,” contradicting and negating the thesis (negation); and the tension between the two being resolved by means of a “synthesis” (affirmation) (Störig 2002).
- Chapter 42 of the Dao De Jing outlines a numerological cosmology based on a dialectical monism. In the following analogously: “The Tao bore One; One bore Two; Two bore Three” (Lao Tzu 1994).

On the contrary, the very unique logic of negation in Indian logic, particularly the emphasis on “emptiness” in Buddhism, does not stress the integration of thesis and antithesis, rather than the negation of thesis, antithesis, and synthesis as well.

2. Modern logic descends mainly from the ancient Greek tradition, which was particularly characterized by Plato and his pupil Aristotle. In this regard, logic can be mainly understood as a formal systematic study of principles of valid inference and correct reasoning. A very basic set of according principles is provided by the three laws of thought, which are attributed to Aristotelian syllogism. They were fundamental for the development of rational discourse in Jewish, Christian, and Muslim epistemology. The laws include:

- (a) Law of identity: A equals A.
- (b) Law of noncontradiction: A does not equal not-A.
- (c) Law of excluded middle (“tertium non datur”): A cannot be both A and not-A (Boole 2009).

The resulting assumption by Aristotle is still present in contemporary fields of formal logic and positivistic sciences: existence (A) and inexistence (non-A) categorically exclude each other.

However, this postulate is not valid in the perspective(s) of dialectic logic. Two examples are:

- According to Hegel’s dialectical logic of integration, existence and inexistence are integrated into the higher category of “becoming.”
- According to Nāgārjuna’s dialectical logic of negations, neither existence nor inexistence is with essence. The ultimate truth lies in nonduality (Störig 2002).

To summarize, systematic reasoning in classic and modern logic implies using contradictions in order to distinguish between mutually exclusive aspects like “valid or invalid” and “true or false” and to isolate them. However, reasoning in dialectic logic leads to an overcoming of contradictions through inclusion or negation into increasingly holistic perspectives.

Logic in Buddhism, Fig. 1 Different logic styles

Particularly the negative dialectic Buddhist logic is a method of *reductio ad absurdum* for any concept which discerns “valid vs. invalid,” “true vs. false,” etc. (Fig. 1).

Modern Applications of Buddhist Logic

Since the mid-twentieth century, the term “dialectic logic” has increasingly been considered with regard to the question of how dialectic logic could enrich modern sciences, as these are still mostly influenced by classic logic and positivism. The sociopsychologist Erich Fromm was one of the first to establish this term (Fromm 1989), and Johan Galtung, one of the cofounders of peace studies, was one of the first to implement it within the context of holism in modern sciences (Galtung 2008). Both Fromm and Galtung discussed this term in a context of societal criticism. They attributed dialectic logic, understood as “holistic” and inclusive thinking, to Eastern cultures. By contrast, they attributed Aristotelian logic exclusively to Western culture. In this regard, Aristotelian logic is usually

understood as an “atomistic” thinking culture, which concretely determines concepts like “true” as opposed to “false” and “good” as opposed to “bad” (Fromm 1989; Galtung 2008). However, this categorical East-West attribution cannot explain the very similarly distributed appearance of fundamentalism and radicalism, which is driven by “either-or” thinking in both Western and Eastern cultures. Furthermore, neither the historical development of dialectic philosophies in Greek (e.g., Heraclites, Neoplatonism) and Western (e.g., German idealism, Marxism) cultures nor the integrative pioneering works of specifically Western theoreticians like Fromm or Galtung should be underestimated.

Due to its holistic focus, dialectic logic has increasingly been considered in contemporary emerging multidisciplinary approaches. The reinterpretation of Buddhist logic and its application to innovative methods of conflict resolution provide a very current and significant example. With this regard, Johan Galtung clarifies that theory and practice of conflict, “defined as mutually exclusive-incompatible-contradictory

Logic in Buddhism, Fig. 2 Application of the Buddhist tetralemma – five basic outcomes of a conflict

goals,” usually imply a “dilemma logic,” based on the above-mentioned Aristotelian episteme of *tertium non datur*. This implies the assumption that, if the goal of both the first and the second conflict party has been realized, they cannot both be true within the perspective of the dilemma logic. On the contrary, the Buddhist tetralemma logic opens new realities and possibilities for conflict resolution, negating the assumption that the conflict parties represent a “single truth.”

As discussed previously, Buddhist dialectic logic expands the dilemma perspective of true-false to a tetralemma, adding both true and false and neither true nor false. Galtung also introduces a half-half (including 50–50 and any other percentage division) in order to arrive at a pentalemma. His model gives an overview of possible outcomes of a simple conflict over two goals: goal 1, goal 2, compromise, negative transcendence (neither-nor), and positive transcendence (both-and) (Galtung 2008) (Fig. 2).

Another modern application of Buddhist logic in theory and practice of conflict resolution is the tetralemma work of Matthias Varga von Kibéd and Insa Sparrer, who modified the method of systemic constellations with Nāgārjuna’s logical figure, including:

- “Either”
- “Or”
- “Both”
- “Neither”
- Consequently “Nothing of all that and even not that” (Sparrer/Varga v. Kibéd 2009).

Dialectical Monism

Dialectical monism holds that the ontological reality is ultimately a unified whole. Using the example of the Yin Yang symbol, essential unity is that of complementary polarities, which are opposed in the realm of experience and perception and cosubstantial in a transcendent sense.

Nyāya

Nyāya (Sanskrit for “recursion,” used in the sense of “syllogism, inference”) is the name given to the school of logic in Hindu philosophy. It is one of the six orthodox or astika schools of Hindu philosophy.

Nondualism

Nondualism can be regarded as the very peak of consequent application of dialectical reasoning. Nondualism holds that ultimate truth is not categorizable, beyond mutually exclusive categories of thought. The famous first lines of the Chinese Dao De Jing provide an appropriate example:

The Way that can be told of is not an unvarying way;

The names that can be named are not unvarying names.

It was from the Nameless that Heaven and Earth sprang;

The named is but the mother that rears the 10,000 creatures, each after its kind. (Lao Tzu 1994)

Accordingly, any concept, implying a separative differentiation, is regarded as illusive. Paradoxical statements like “form is emptiness and emptiness is form,” cited from the famous Mahāyāna Diamond Sūtra (Sanskrit: Vajracchedikā Prajñāpāramitā Sūtra), are typical to nondualist statements. It is noteworthy that nondualist statements appear highly paradoxical to conventional thought. Any concept, even the difference between saṃsāra (meaning the cycle

of birth, life, death, and rebirth) and *nirvāṇa* (meaning the liberation from *saṃsāra*) or absolute and relative truth, is considered to be “nondifferent.” In Buddhism, nondualism is particularly considered part of *Mahāyāna* tradition (including, for instance, Zen and *Mādhyamaka*) and partly also in *Vajrayāna* Buddhism (for instance, in the *Dzogchen* practice). In Hindu philosophy, nondualism is central to *Advaita*, which is the most influential and dominant subschool of the *Vedānta* school.

Consequently, nondualist spirituality does not regard enlightenment as an achievable end of a path (as stressed, for instance, in the *nirvāṇa* concept of *Theravada* Buddhism), rather as having always been inherent to the path itself (such as, for instance, in *Mahāyāna* and *Vajrayāna* Buddhism). The ultimate truth is therefore regarded as *omni-inherent* and cannot be separated, even from relative truth.

Theravada Buddhism

Theravada (“The School of the Elders,” the most important and only remaining school of the “*Hīnayāna*” tradition, meaning “The Small Vehicle”) is the oldest surviving Buddhist school and has a widespread following in Sri Lanka and Southeast Asia. Accordingly, it is relatively conservative and generally closer to early Buddhism. *Theravada* implies meditation techniques like *saṃatha* and *vipassanā*. In *Theravada*, the individual realization of *bodhi* (awakening) is the ultimate goal and usually equated with the term “*nirvāṇa*.” On the contrary, in nondualist *Mahāyāna* and partly *Vajrayāna* tradition, *nirvāṇa* does not stand for complete enlightenment, since it still implies an opposition (*saṃsāra*).

Mahāyāna Buddhism/Vajrayāna Buddhism

Mahāyāna (“The Great Vehicle”) developed from *Theravada* and is found throughout East Asia. It includes the traditions of *Mādhyamaka*,

Zen, *Nichiren* Buddhism, *Tibetan* Buddhism, *Tiantai*, *Pure Land*, and *Shinnyo-en*, among others. According to the teachings of *Mahāyāna* traditions, “The Great Vehicle” refers to the path of seeking complete enlightenment for the benefit of all sentient beings, also called “*Bodhisattvayāna*.” In contrast to *Theravada*, the individual achievement of *bodhi* (awakening) is therefore not the ultimate goal in *Mahāyāna* Buddhism. The Buddha nature (Sanskrit: “*Tathāgatagarbha*” or “*Buddha dhātu*”) is considered to be present in all beings, creating an immanent link to the awakening, constituting the deathless “essence of the self.” As a consequence of *Mahāyāna*’s nondual philosophy, any being is therefore regarded as already enlightened, whether aware of it (meaning “awakened”) or not.

Vajrayāna (often translated as “The Diamond Vehicle”) or “*Tantric Buddhism*” is mainly practiced in Tibet and Mongolia and recognized as a part of the third branch of Buddhism, while others classify it as a part of *Mahāyāna*. *Vajrayāna* techniques, including *Dzogchen* and *Mahamudra*, are aimed at making it possible to experience the Buddha nature prior to full enlightenment.

Positivism/Neopositivism

Positivism is a philosophical approach, based on the idea of objective truth, meaning that observational evidence together with its logical and mathematical treatment is the exclusive source of all worthwhile information. The positivist approach has been a recurrent theme in the history of Western thought from the ancient Greeks to the present day but has been significantly developed from the early nineteenth century until the mid-twentieth century. Postpositivism, mainly influenced by Sir Karl Popper’s falsification theory and Thomas Kuhn’s theory of the paradigm shift, still maintains the idea of objective truth, but believes that human knowledge is based not on unchallengeable, rock-solid foundations but rather upon human conjectures.

Informal Logic

Informal logic is the study of natural language arguments, particularly the study of fallacies. The dialogues of Socrates/Plato are good popular examples of informal logic.

Formal Logic

Formal logic is the study of inference with purely formal content. The works of Aristotle contain the earliest known formal study of logic and have been expanded into modern formal logic.

Symbolic Logic/Mathematical Logic

Symbolic logic is the study of symbolic abstractions which capture the formal features of logical inference. It can be further divided into propositional logic (sentential logic) and predicate logic (see, e.g., Gottlob Frege). The latter provides the foundation of mathematical logic, which is an extension of symbolic logic into other areas, including the study of model theory and proof theory, among others.

[Rational thinking in Islam](#)

Description

In the Muslim middle ages, logic was a discipline borrowed mainly from ancient Greece that made it possible to establish rules of sound reasoning. It was, in other words, a way to discover truth independent of theological arguments stemming from revelation. Over the centuries, Arabic philosophers developed logic into an original system.

Logic developed through the Syriac language during the reign of the ‘Abbasid Caliph al-Ma’mūn (813–833), though a version of the *Topics* may have been made at the time of the third ‘Abbasid Caliph al-Mahdī (775–785). The translation movement focused on Porphyry

(d. 304)'s *Isagoge*, Aristotle's *Categories*, *De interpretatione* and *Prior Analytics*, Galen (d. 200)'s *Introduction to logic*, and on works by Aristotle's commentators such as Theophrastus (d. 287 B.C.), Alexander of Aphrodisias (d. 222), Themistius (d. 387), Ammonius (d. 520), and John Philoponus (d. ca. 580). In line with the Alexandrian school and Syriac tradition, the *Rhetoric* and *Poetics* were also considered parts of Aristotle's collected logical writings known as the *Organon* (instrument of reasoning); Porphyry's *Isagoge* was placed at the beginning as an introduction (Inati 1996, pp. 802-803; Street (2008)).

One of the first systems of logic was that of the tenth-century Ikhwān al-Safā' (the Brethren of Purity), which appears in their encyclopedia of sciences at the end of the first section on the propaedeutical sciences. They paraphrase with some originality the *Isagoge*, *Categories*, *De interpretatione*, and the *Prior* and *Posterior Analytics* (Baffioni 2008, p. 105).

Until the end of the tenth century, the most important logicians, apart from al-Fārābī (d. 950), were Christians. With the Baghdad Peripatetics, characterized by the work of Abū Bishr Mattā ibn Yūnus al-Qunnā'ī (d. 940) and al-Fārābī, logicians focused on the doctrines in the *Organon* of Aristotle, the "first master" of logic. The Arabic philosophers produced summaries and commentaries that merged Aristotle with Stoic doctrines, often in an original way. Among them were Abū Bakr al-Rāzī (d. 925), al-Fārābī (d. 950), Ibn Sīnā (the Latin Avicenna, d. 1037), and Ibn Rushd (the Latin Averroes, d. 1198).

The Farabian tradition passed to Spain in the tenth century, where it was enlarged by Averroes, who was concerned with this kind of exegesis. Ibn Sab'īn (d. 1269/71) would also subsume the ideas of the Ikhwān al-Safā'.

By the end of the twelfth century, Aristotle was no longer a significant source for Arab logicians in eastern Islam: his place was filled by Avicenna, who reinterpreted Aristotelian logic in an original way.

In the thirteenth century, Fakhr al-Dīn al-Rāzī (d. 1209), an anti-mu'tazilite theologian (the

Mu'tazilīs were the most rationalist among Muslim theologians; their school originated in the eighth century and it is not usually accepted by the Sunnīs), and a critic of Avicenna, founded a "western" school of Persian logicians (Rescher in Arnaldez (1991), p. 450); another major follower and commentator on Avicenna was Nasīr al-Dīn al-Tūsī (d. 1274), who criticized Fakhr al-Dīn al-Rāzī. Najm al-Dīn al-Kātibī (d. 1276) discussed logic with both of them. His *Al-Risāla al-shamsiyya* ("The logic for Shams al-Dīn": d. 1284, a patron of theology, sciences, and art.), based on Avicenna's teachings, introduced logic to the madrasa. But by this time, logic was confined to narrowly formal questions and no longer ranged over the subjects discussed in the *Organon* of Aristotle.

From about the end of the fourteenth century, Arabic logic is marked by lack of creativity and reiteration of earlier views, as demonstrated by al-Urmawī (d. 1283)'s *Matāli'* *al-anwār* ("The rise of the lights") and the commentaries on it and on al-Kātibī. The history of Muslim philosophy from this period onward requires further research, which may change this provisional judgment (Rudolph 2004, pp. 91-98).

In recent times, Arabic logicians have followed the main western schools. The Moroccan philosopher Mohammed al-Jabri, however, deserves special mention. In evaluating the history of Muslim thought, he emphasizes Averroes' scientific approaches, a basic component of which is found in the logic-based *bayān* (elucidation) of the tenth-century theologian Ibn Hazm (d. 1064): according to Jabri, these approaches should be resumed by modern Muslims to bridge the gap with the West.

Self-identification

Science

Logic – the search for truth through undisputable arguments – is self-evidently a science. But the Peripatetics saw it as a scientific "tool," and so the Arabs were soon faced with the opposition between this view, which was supported by the use of the

term *ala* (instrument) like Greek *organon* to signify logic, and that of the Stoics, who considered logic as part of philosophy. The Muslim Neoplatonists tried to reconcile these positions. For the Ikhwān al-Safā', logic was not an instrument of science but a true science, perhaps the highest: they called it "the scale of sciences" through which wise men could discern "true from false in speeches, right from wrong in opinions, truth from vanity in beliefs and good from evil in acts." Al-Fārābī called logic "the mistress of the sciences" because of its effectiveness in complementing them. Avicenna considered logic "the servant of the sciences" in that it was a means of acquiring them, but made it an integral part of his treatises.

Religion

If its instrument is human reason, logic cannot be a religion. But it was of basic importance in theological debates: logic was soon employed by Muslim thinkers in internal and external polemics, especially with Jews and Christians, on topics such as freedom, determinism, and the Trinity.

Arabic theologians and jurists had already made use of *ijtihād* (the free use of reason) in opposition to *taqlīd* (imitation). The Hanbalīs (followers of the school of theology based on the teachings of Ahmad Ibn Hanbal (d.855), hostile to speculative theology (*kalām*) and to esoteric Sufism, accepted that reason is a gift of God in that all knowledge comes from God; the Ash'arīs (The followers of the school of theology on which Muslim Sunnism is based after its founder's name, Abū 'l-Hasan al-Ash'arī (d.935–936), a former Mu'tazilī), distinguished between various types of ► [demonstration on the basis of two terms](#), the most important of which infers what is hidden – for example, the unity of God – from what can be perceived – for example, the multiplicity of existing beings. These demonstrations were probably influenced by Roman and rabbinical laws, but they are roughly contemporary with the earliest surviving logical translation by 'Abd Allāh ibn al-Muqaffa' (d. 757). According to al-Shāfi'ī (d. 820), analogy is a form of reasoning more rigorous than the simple comparison of similar cases.

Characteristics

Logic has its own rules and subject matter on which all other disciplines, including theology, should rely.

Relevance to Science and Religion

Muslim philosophers and scientists considered the relationship between revelation and reason or religion and philosophy to be crucial. Philosophers, who were deeply influenced by Aristotle, considered reason to be a major gift of God and believed that science had to be grounded on Him. This implied that logic was "justified" in a religious-oriented system of thought such as that of the Muslims. Many Muslim theologians such as the *zāhirī* Ibn Hazm and the *ash'arite* al-Ghazālī (d. 1111) developed Greek logic to suit their culture and aims. The *zahirī* is a theologico-juridical school that relies exclusively on the literal sense of the Quran and of tradition, rejecting rational opinion analogy: although the latter is retained by al-Shāfi'ī, d. 820, usually considered at the origin of this school.

Ibn Hazm knew Aristotelian logic well, but he also considered conditional syllogisms following the Stoics. His aim was precise understanding of the divine word without human interpretation, as part of which he justified logic by means of Qur'anic verses (e.g., 55: 3), arguing that if logic were ignored, the structure of divine language would remain hidden. Without rejecting logic, Aristotle's in particular, Ibn Hazm reduced it to an instrument for the evaluation of names and of their meanings and whether they are isolated or connected in speech. In doing so, he transformed the logic of Aristotle into *Zāhirī* logic (Arnaldez 1991, p. 446).

Al-Ghazālī introduced Greek logic into judicial issues, arguing that it was the basis of juridical syllogisms against the claim that it could be harmful to religion. But of course logic cannot refute or prove religion.

Other theologians refuted logic completely: Ibn al-Salāh (d. 1245) saw logic as a means of access to philosophy, of which he had

a low opinion; Ibn Taymiyya (d. 1328) reproached al-Ghazālī for introducing Greek logic into the *usūl al-dīn* and *fiqh*, though he conceded that as a formal system logic was unobjectionable; and al-Suyūṭī (d. 1505) condemned Hellenistic logic because for him every speculation should be submitted to religious tradition.

Another basic and much debated issue was whether God himself was subject to logical rules.

Sources of Authority

The first authorities were the translators. The most famous translators of Greek logic into Arabic besides Ibn al-Muqaffa' and Abū Bishr Mattā were Yuhannā ibn al-Bitrīq (d. 830), Hunayn ibn Ishāq (d. 877), his son Ishāq ibn Hunayn (d. 910), his nephew Hubaysh ibn al-Hasan al-Dimashqī (d. 890), Abū 'Uthmān al-Dimashqī (d. 920), Ibrāhīm ibn 'Abd Allāh (d. 940), and Yahyā ibn 'Adī (d. 973).

Their authority depended on the accuracy of their collation of available manuscripts, their knowledge of Greek, and their comprehension of the ancient authors.

Then came the philosophers, who developed ancient logic in new ways.

In the Ikhwān al-Safā', who earlier examined the "quadrivium" sciences – arithmetic, geometry, astronomy, and music – the logical treatises appear to substitute the "trivium" – grammar, rhetoric, and dialectics. There is no place for poetry or dialectical and rhetorical devices in the encyclopedia, which would increase dissension among the learned (Baffioni 2008, p. 108; Baffioni (2008)). And although grammar is the basis of verbal communication, the Ikhwān never approached it as a science: instead, they examined the technique of the "universal" form of language – logic – distinguishing linguistic logic and philosophical logic, the first as a premise of the second. The Ikhwān appear to be only partially in accordance with their contemporary al-Fārābī, perhaps because of the religious aims of the encyclopedia, which was premised on a sound method for discovering

truth. In the context of the new form taken by Aristotle's *Organon*, the Ikhwān added the "individual" to the five predicables – genus, species, difference, property, and accident – discussed in the *Isagoge*, and al-Fārābī spoke of five types of syllogism: demonstrative, dialectical, sophistical, rhetorical, and poetical, which expressed certitude, presumption, falsehood, persuasion, and imagination.

In his commentaries, which followed the method of the commentaries on the Qur'ān, al-Fārābī aimed to clear away misinterpretations of Aristotle's text. This task was taken over in Andalus by Ibn Bājja (the Latin Avempace, d. 1139) and above all by Averroes, who was the most faithful to Aristotle, whom he is reputed have followed to the letter. He began his commentaries on logical works with the *Categories* and ended them with the *Sophistics*; he also commented on the *Rhetoric*, *Poetics*, and *Isagoge* but did not consider them parts of logic.

In the thirteenth century, Arabic logic influenced by Greek passed into the Latin tradition. The Latin distinction into *logica vetus* and *logica nova* is inappropriate in Arabic, as the whole range of Aristotelian logic was available by about 900. Rather, it is Avicenna – who emphasized the novelty of his "Oriental philosophy" against the "Christian simpletons of Baghdad" – who has to be considered as marking the beginning of a new phase in the history of Arabic logic, at least in eastern Islam. But medieval Latin translators set aside Arabic texts dealing with Avicenna's system and translated other less influential texts by al-Fārābī and Averroes that concentrated on Aristotle and addressed thirteenth-century western logical concerns. The insignificance of Aristotle's logical system in the Avicennian tradition distorted western appreciation of the importance of logicians writing in Arabic.

Tony Street (2005, p. 247) considers al-Kātibī's *al-Risāla al-Shamsiyya* to be an important reference text because until the twentieth century, it was commonly the first text on logic studied by Sunni Muslims. Thus, foreign science came to be embraced by Islam at its educational heart, the *madrasa*.

Ethical Principles

Poetry, rhetoric, and above all dialectics do not aim to discover truth, and so do not advance religious queries and debates. Hence, an entire part of ancient logic was ignored at the beginning of the translation movement. The *Posterior Analytics* were introduced later after a break with the Syriac tradition that stopped the study of logic at the assertory syllogisms (end of *Prior Analytics* I, 7). Al-Fārābī's great innovation was to enlarge inspection to the whole logical *corpus*. But his statement that the Syriac limitation was due to a decree by the Synod was later recognized as a forgery: it probably corresponded with the shortened version of the sixth-century Alexandrian *curricula* available to the Syrians, which was translated into Arabic in the second half of the eighth century.

On the other hand, logic was for Muslim philosophers no longer just a key to knowledge: it was also a key to happiness – the ultimate aim of religion in that the more learned each soul becomes regarding intelligible objects the closer it is to the Universal Soul and to celestial pleasures (Abed 1991).

Key Values

Logic was also called *mīzān*, the balance, because it weighs arguments and proofs; it was also known as *mī'yār*, the standard, and *mihaqq*, “the test.” Logic assumes for itself a universal value insofar as it is concerned with intelligible things before which all men are equal (Inati 1996, p. 808).

Conceptualization

Nature/World

The Ikhwān al-Safā' link logic with cosmology in that it deals with concepts corresponding to things, that is to say, entities emanated by God on to the neoplatonic hypostases subsumed in their system and later on to individual human souls. Concepts are intelligible objects that

people represent in their minds having experienced them through the senses.

The Ikhwān preach the conformity of logic with existing beings, so logic is linked to their neopythagorean conception of the correspondence between numbers and existing (= numbered) beings.

Human Being

Nutq, language, is in Arabic the distinctive mark of humans among animals. The Arabic name for logic derives from the same radicals – *mantiq*, a synonym of *kalām* (language) has come to refer almost exclusively to peripatetic traditions of distinguishing a good from a bad argument; it was developed in this sense in the translation period.

Life and Death

The concepts of “life and the origins of death” are not of interest within Arabic logic.

Reality

In line with Aristotle, knowledge is divided into two types: conception (*tasawwur*) and assent (*tasdiq*) (Inati 1996, p. 806). Conception is the mental grasping of an object independent of any assertion as to its correspondence with external reality. Assent is based on asserting the correspondence of a mental object and the external reality; this assertion can be true or false, even though occasionally the term “assent” is used in the sense of true judgment. Following Themistius and the Stoics, the Arabs also studied conditional propositions.

Knowledge

Science is the form of what is known in the soul of him who knows.

Truth

A sound syllogism leads to the discovery of truth, just as demonstrations in juridical matters are based on the divine books.

Perception

As in Aristotle, intelligible objects come to be represented in minds only after they have

been experienced through the senses. Sensory perception is hence the essential first step in acquiring abstract knowledge.

Time

Logical demonstration obviously develops in time. But Avicenna emphasized how prophets received knowledge from God all at once, which is unlike logical processes. He calls such prophetic knowledge *hads*, intuition (on intuition in Avicenna see Street (2008)). Although it is immediately acquired, this knowledge is the same in terms of quality as syllogistic knowledge, which is acquired gradually.

Consciousness

A famous debate occurred in about 932 between the leading logician of his time, the nestorian Abū Bishr Mattā and the Muslim grammarian Abū Saʿīd al-Sīrāfī (d. 979), a commentator of Sībawayh (Endress 1986; Inati 1996, p. 810; Urvoy 2006, p. 241; Baffioni 2008, p. 109).

The basic issue was that while languages are each proper to a single people, logic may claim to be a universal language because it concerned with intelligible things and ideas, at which level all men are equal. The subject of logic is intelligible things in that they have different states that in the course of the explanatory phrase and proof lead from the known to the unknown. There is a connection between logic and language, but neither language nor grammar is the objective of the logician, and although logic cannot be reduced to the grammar of a language spoken by a particular people, grammarians need logic.

This is denied by Abū Saʿīd, who states that intelligible things are only reached through a language with its nouns, verbs, and particles. Logicians are criticized for putting people off with their technical terms. The specificity of a language has greater value than logic, the more so when in a translation logic may no longer explain original significations. According to Abū Saʿīd, it was a Greek who instituted logic according to the language of his people. How could this logic be imposed upon other people?

To preach the study of logic is to preach the study of the Greek language. And logic did not prevent the Greeks from falling into error and moral evil.

But the fact that Abū Saʿīd did not recognize a logic common to everybody brings to light a central issue: can logic suppress differences in opinions and in speculation? How could a single individual succeed in this? Are there not diverse mentalities that are irreconcilable in their diversity? (Elamrani-Jamal (1983) in Urvoy (2006), p. 240).

Abū Saʿīd demonstrates the existence of a certain Arabism that opposed everything Hellenic on the religious basis that God revealed the Qurʾān in “clear Arabic language” (16: 103). Logic was seen as an element of foreign civilization that threatened the Arabic language and grammar and even Islam. Only Yahyā ibn ʿAdī, a pupil of Abū Bishr, succeeded in identifying a universal grammar – logic – from the particular grammar that governs each language. That the Holy Book considered to be the true Word of God, and that God spoke in Arabic, implied that everything linked to Islam can also be considered as “Arabic,” independently from its geographical origin.

Rationality/Reason

Reason is the main basis for logic. It is not to be thought, however, that reasoning was unfamiliar in Islam before the foreign sciences passed into Arabic. Juridical sciences had already developed a method of reasoning whose function was similar to that of logic with respect to philosophy.

Mystery

The concept of “mystery” is not of interest within Arabic logic.

Relevant Themes

Logic involves the relationship between revelation and reason and, in the case of Arabic logic, the attitude toward Islam. Many medieval theologians tried to reconcile literal observance of the

divine Word with the existence of universal and necessary logical laws, and even tried to define the relationship between them and God. On the other hand, philosophers – perhaps for the sake of consistency – tended to ignore this issue and place God “beyond” such laws. The problem has continued to exercise scholars since the early twentieth century.

Applied logic; Argumentation theory; Critical thinking; Practical logic; Practical reasoning

Description

Under the heading of informal logic are comprehended several expressions of the practical turn in logic: from technical, artificial, and formalized language to natural language; from deduction and demonstration in science to argumentation in everyday life; from scientific and theoretical models of reasoning in search of laws and principles to practical patterns of reasoning leading to action; and from pure to applied logic to arguments. Although there are differing emphases among them, all these expressions, namely, theory of argumentation, practical logic, applied logic, and critical thinking, share a common ground with informal logic.

Informal logic is a young discipline that emerged during the last quarter of the twentieth century. But in another sense, it is one of the oldest for its themes and concerns are somehow the same as those found in a substantial part of Aristotle's *Organon* (adding his rhetoric which was excluded very early from the logic corpus). Informal logic is not always sensible to the

history of logic and does not have to be. On taking the history of logic into account, it is easy to see that this new age of logic is equal to a renaissance of dialectic and rhetoric, both excluded from the formal, mathematical, and symbolic logic of the twentieth century. However, it is not necessary to go as far back as Aristotle to try to understand the main traits of informal logic. The most important features of informal logic will rather be made manifest through a contrast with contemporary formal logic.

But this relation to formal logic is not without problems or, at least, it is not univocal. First, it can be characterized as a strong contrast between formal and informal logic in different ways: (1) Informal logic rivals with formal logic in order to do what the other cannot, namely, to account for the everyday reasoning and real argumentation that occur in a natural language. That is something informal logic does as far as it questions the concept of validity in the deductions of formal logic. It even questions the traditional difference between deductive and inductive arguments. Consequently, it opens a new and unknown field of research which cannot be approached with the mere instruments of formal logic. (2) It can also be characterized as a complement to formal logic (Jacquette 2007) in as far as it conceives of informal logic as a branch of logic (Johnson 2006). (3) Finally, it can be characterized as a continuum with formal logic thus keeping the formal ideal alive, something that can also be assumed for natural language and for arguments in everyday life (Gabbay et al. 2002).

The contrast between informal and formal logic begins with the challenge of the notion of validity in formal logic. This makes the strong commitment of traditional formal logic to deduction characterized as deductivism manifest. When informal logic distinguishes between bad and good arguments, the privilege and hegemony of deduction comes to an end. The traditional formal criterion of validity/invalidity gives way to a new manner of analyzing arguments according to their power of persuasion, in other words, to their effectiveness. But the good/bad distinction diverges from the valid/invalid one by

admitting degrees (better/worst), and in this respect, it looks like the strong/weak distinction of the inductive arguments. The difference rests on the fact that whereas in the inductive arguments the strong/weak criterion is measurable, therefore quantifiable, as probability and statistics make evident, the good/bad distinction is a qualitative criterion which depends on subjective appreciation. For this reason, the strong/weak distinction in the inductive arguments is calculable although not necessarily apt to formalization, while the good/bad criterion is neither calculable, at least within the scope of statistics and probability, nor liable to classical formalization. The other consequence of this new approach is that it makes the previously unchallenged distinction between deductive and inductive arguments irrelevant.

Formal logic has depended on its distancing from natural language which is plenty of ambiguities and paradoxes. Formalization was the strategy used to simplify language and to make it univocal and consistent. The consequence is a formal language, rigorously regimented but lacking in power of expression. Informal logic emerges, then, as a necessity for linking logic back to argumentation in natural language and everyday life.

This now leads to a final contrast concerning the content of thought. Formal logic had developed infallible models of inference, that is to say, models which are valid independently of the content. This was possible thanks to the previous formalization of language which eliminated its vagueness and ambiguity. But, when informal logic begins considering arguments in natural language and relevant for everyday life, content also begins to matter. It even inverts the traditional relation between form and matter. Instead of the precedence of forms which are to be infallibly applied to diverse cases and contents, informal logic is sympathetic to the pragmatist thesis that formal inferences are to be explained through the capacity to distinguish between a good and a bad material inference.

Besides these contrasts, the following are the main themes or essentials of informal logic: (1) A broadening of the notion of argument

(Blair 2006) that includes everyday discourses, advertising, and public opinion. (2) Dialogical argumentation (Vega Reñón 2007). (3) Evaluation of arguments, including the task of detecting implicit premises and the reconstruction (repair) of arguments, as well as the evaluation of premises in relation to the participants in a discussion or to the particular audience. (4) A special concern with fallacies, beyond the traditional formal approach. That means considering fallacies as contextualized habits of inferring and not just as cases of formal incorrectness (Groarke 2011).

Self-Identification

Science

Teaching logic is one of the main components of informal logic, basically, because one problem had been the lack of relevance of traditional formal logic for the instruction leading to involvement in public argumentation and to the analysis and evaluation of arguments. The classroom turned into an artificial environment where examples were prepared with the preconceived aim of instructing the students in some aspects or schemes of demonstration. But students demanded something more involved with reality, with real arguments, with arguments on vital issues, issues that had not yet been resolved, and issues that were still alive. Informal logic, however, is not just an area concerned mainly with the teaching of logic. It is also an area of theoretical research linked to other disciplines such as linguistics, communication, rhetoric, argumentation, artificial intelligence, cognitive psychology and theory of discourse.

Characteristics

Informal logic is different from traditional formal logic in the way it depends, first, on natural language; second, on context; third, on social interaction; and finally, on agent, that is to say, on practice. All of these dependencies have intentionally been overlooked in traditional formal

logic because this is precisely the aim of examining pure thought: the laws of thought or the principles of reasoning considered independently of the contingencies and ambiguities of natural languages and of the diverse particular practices. Such principles are also considered for all possible contexts and situations and are, therefore, valid for all audiences, which is the same as being independent of the audience.

Relevance to Science and Religion

When religion competes with science because science has somehow lessened the authority of its doctrine and beliefs, religion is found in the situation of having to defend herself against the loss of consensus by getting involved in disputes with the representatives of science who sustain the incompatibility of the two ways of approaching life and reality. Informal logic has to do with the argumentative dynamic of this confrontation. Nevertheless, religion does not always adopt an attitude of rivalry toward science. Likewise, science is not always in conflict with religion.

Sources of Authority

There are some antecedents of informal logic which express different ways through which this new approach to logic has emerged. In 1958, two significant works appeared: Toulmin's *The Uses of Argument*, calling attention to the practical circumstance of arguments, and Perelman's and Olbrechts-Tyteca's *The New Rhetoric: A Treatise on Argumentation*, putting forward the problem of persuasion of the audience. In 1970, Hamblin published *Fallacies*, offering for the first time an informal approach in which fallacies are not just violations of the rules of formal deduction.

Since the 1970s, the discipline of informal logic has become known through the names of Ralph H. Johnson (2006; Johnson et al. 1996), J. Anthony Blair (2006), Douglas Walton (2006), and John Woods (2004) and their

multiple books and articles. On the side of the theory of argumentation, the relevant names are Frans H. van Eemeren (1996), R. Grootendorst, and C. Plantin.

In 1978, the First International Symposium on Informal Logic took place and the *Informal Logic Newsletter*, which later became the review *Informal Logic*, began to appear. Other journals in the field are *Argumentation, Philosophy and Rhetoric* (since 1968), *Teaching Philosophy, Rhétorique et argumentation*, and *Argumentation et Analyse du Discours* by the group ADARR (Analyse du Discourse, Argumentation et Rhétorique).

The discipline is also active through the following organizations: The Association for Informal Logic and Critical Thinking, International Society for the Study of Argumentation, Centre for Research in Reasoning, Argumentation & Rhétoric, and the ADARR group (Analyse du Discourse, Argumentation et Rhétorique).

Ethical Principles

Informal logic is committed to the idea of pluralism and tolerance; every individual or person is in the situation of having to defend her own opinions, to revise them in connection with her most important beliefs. At the same time, every person has the duty of considering others' reasons and motives. Informal logic encourages dignity and respect for diversity of opinion and belief, not in the sense that "anything goes" but in the sense of taking part in the game of giving and asking for reasons.

Key Values

Since informal logic promotes a pluralistic worldview, tolerance and respect are the primary key values. Insofar as informal logic is concerned with argumentation and the role agents play in it, honesty is another key value. And, since it is a logical approach of the arguments in everyday life, rigor is also a key value. This also supposes freedom of thought and expression as a value and,

thus, implies the option for democracy against any kind of authoritarianism and totalitarianism.

Conceptualization

Nature/World

From a scientific and formal point of view, world and nature are the place where we can verify our knowledge or that which is the object of our knowledge, this object being very complex and approached only through its manifold aspects, thanks to manifold disciplines. All of this implies a certain order among the disciplines according to their dependence on others. But from the perspective of informal logic, nature and the world are the place where we humans act rationally. Action configures the world different than knowledge and the sciences do. Whereas knowledge gives an objective, nonperspective view of the world, action configures the world according to means and ends. This happens in the social context of human action where agents coordinate their interests and practices, and the result is a world consisting on a web of interrelated references. While the world, from a scientific perspective, tends to be one and the same for everyone, from a practical perspective, multiple world views are the result of multiple social practices and ways of interacting among agents, thus, generating multiple contexts. The resultant pluralism and relativity to context is something to be accounted for by informal logic.

Human Being

From the point of view of informal logic, the most salient feature of human beings is their rationality. However, human rationality is not merely an individual's attribute or something that can be examined only in respect to individual persons but something that is to be analyzed in a social context and in the context of action.

Life and Death

Informal logic is not directly concerned with life/death concepts, save in the sense of supposing the contingency and finitude of human life and rationality.

Reality

Used to be the hardest concept on which to rely because it designates the most stable, the most independent from ourselves and the least subject to arbitrariness and relativity. But informal logic does not rely on the hard concept of reality which is provided by traditional sciences in the sense of the given “once and for all.” On the contrary, the sense of reality is constructed according to human agency, which, in its turn, proceeds on the basis of beliefs as rules for action. Since there is no univocal set of beliefs on which to base human action, reality becomes plural, the diverse constructions resulting from the different sets of beliefs which rule action. In this sense, reality is subject dependent, agent dependent.

Knowledge

Before the emergence of informal logic, knowledge was easily identified with science and scientific knowledge. The formal approach to logic was then directly linked to science in the sense of being considered the canon of demonstration and proof. But in the last decades, sciences have evolved from the pure logic of demonstration, which used to distinguish them from other kind of discourses, to a more argumentative, therefore pluralistic and contingent way of explanation. Over more, knowledge and science were defined as opposed to opinion, also assuming the corresponding opposition between demonstration and argument, so that science was not a matter of argument. But, as far as science has been permeated by argument, its opposition to opinion ceases as does the opposition between demonstration and argument. Compared to the traditional definition of knowledge as “justified true belief,” informal logic would rather agree with a concept of knowledge in which the justification plays the central roll, prior even to truth itself.

Truth

Traditional formal logic is concerned with schemes of inference insofar as they are truth-preserving, meaning that they are forms of transmitting truth from the premises to the conclusion in an argument. However formal logic is not directly concerned with truth but with validity,

that means, with the infallible forms of transmitting or composing (by means of the logical connectives) truth. Therefore, formal logic does not decide on the truth or falsity of our atomic statements and beliefs but merely on the validity or nonvalidity of passing from the premises to the conclusion, no matter the content. In this sense, the sciences, traditionally considered, strongly depend on formal logic since their search is for objectivity, which is the same as truth in respect to reality. Their demonstrations, therefore, are regimented by the laws and principles of formal logic.

Informal logic is still farther from truth than formal logic is because it does not even rely on the concept of formal validity and the truth preserving function. For informal logic, the content of the premises is important, and, therefore, the relationship between consequence and conclusion acquires other nuances: ¿how strong or how good are the premises for the conclusion? Content is now relevant for the argument. Instead of being true or false, premises are to be accepted or rejected, and that is something that occurs contingently according to the agent or interlocutor and her beliefs. The acceptability of the premises now occupies the place of truth. Goodness of the argument occupies in informal logic the place validity had in the formal approach to logic. Whereas formal validity is a matter of “yes” or “no,” goodness of an argument admits degrees which are determined according to the acceptability of the premises and their relevance for the conclusion.

Perception

It is no longer a neutral input for knowledge but something which, besides our beliefs and opinions, accompanies our action and takes part in our decisions. Perception is no longer the natural and central connection to reality, since it is now contextualized and framed by several attitudes of our mind toward reality.

Time

Two meanings for the concept of time are as follows: first, as a limitation to reasoning, which means a scarcity of time to decide and to act according to a limited set of premises and

conclusions, and second, in the sense of opportunity, the right moment (*kairos*), the context of action in which we happen to reason.

Consciousness

This concept is not explicitly defined within the discipline of informal logic.

Rationality/Reason

It used to be traditionally understood as an impersonal (or suprapersonal) entity which governs human wisdom and behavior, such as a tribunal or court where conflicts among humans were to be resolved, but not by humans. This concept of reason and rationality implied that reason was one and the same for everyone and that rationality was unique. This is what is known as the substantial concept of reason. However, the concept of reason has evolved from this impersonal and substantial view to a human-related one in which rationality is conceived of as essentially committed to the variety of human circumstances and contingencies. Additionally, reason is also involved in human action, not in the traditional sense of being the precedent for action (i.e., what makes it rational) but rather in the sense of reason and rationality being the expression of human practical life and action in a social context. Thus, reason becomes a socially ruled procedure by means of which individuals and groups try to negotiate their interests. This is not a strict logical procedure but one that is better characterized as argumentative and pragmatic, hence its concern with informal logic rather than with traditional formal logic.

Mystery

Considered as something that is not reachable to human understanding, or something that does not belong to the space of reasons, mystery is not an issue for informal logic. However, in a negative sense, informal logic could contribute to the framing of mystery, as the realm on the outer frontier of the space of reasons: inside the space of reasons, all the things humans can argue for or against and act in consequence; outside, the things no one can argue for or against but decide to believe in.

Relevant Themes

From the point of view of informal logic, there are no further issues regarding the engagement of science and religion.

Logic, Predicate

Miguel Palomino

Dpto. Sistemas Informáticos y Computación
(UCM), Facultad de Informática, Universidad
Complutense de Madrid, Madrid, Spain

Related Terms

[First-order logic](#)

Description

Predicate logic is a subdiscipline of logic that had its roots in the last quarter of the nineteenth century, though it had to wait until the second decade of the twentieth century for a solid foundation. Like any other logic, it is concerned with the validity of arguments, though not of any kind: its interest lies in reasoning about what is universally true. As such, predicate logic is especially suited to reason about mathematical statements and can be considered a generalization of Aristotelian syllogisms. Predicate logic goes beyond syllogisms by introducing predicates with arbitrary numbers of arguments and quantifiers that allow to refer either to all or to some of the elements in the universe that is under consideration. It has a proof theory, which consists of a set of rules that describe how to mechanically derive sentences from a given set of premises (and such derivations are called “proofs”), as well as a model theory that assigns meaning to the sentences with respect to structures so that a given sentence is either true or false in a given structure. Predicate logic is sound, meaning that every sentence that can be derived using the rules in its proof theory holds in every possible structure. More importantly, a fundamental result by Gödel in 1929 shows that predicate logic is also complete in the sense that if a sentence is true in every structure, then it can be derived from the empty set of premises (Enderton 2001; van Dalen 2004).

Self-Identification

Science

Logic, and in particular predicate logic, is a formal science. As opposed to natural sciences, knowledge in predicate logic is not obtained through observations and empirical study but from the analysis and processing of certain symbols and rules. It is also formal in the sense that it provides a framework in which reasoning can take place, the form of the argumentation being the only element that determines whether it is valid or not (disregarding any purported meaning).

Characteristics

Predicate logic, with its focus on universally true statements, has proved to be sufficient in principle to formalize and reason about the main bulk of mathematics. In addition, predicate logic satisfies many good properties (such as completeness) that not all variants of logic possess, and it has been shown in a precise manner that a logic more expressive than predicate logic must give up some of these properties in exchange of its additional power (Ebbinghaus et al. 1996). A logic L is said to be at least as expressive as another logic L' if, for every sentence in L' , there exists a sentence in L such that the structures that make the first sentence true are exactly the same as the structures that make the second true. However, different disciplines (like computer science) require other kinds of reasoning, such as probabilistic, subjunctive, temporal, or fuzzy, to name a few. Dealing with that kind of arguments in predicate logic is convoluted at best, while other branches of logic are more appropriate and should be used instead: probabilistic logic, temporal logic, fuzzy logic, etc.

Relevance to Science and Religion

Predicate logic is not interested in the area “Science and Religion; its field of study abstracts from the real world and focuses instead on mental constructions.” It is relevant to it,

though, in the same broad sense that logic in general is: it is a useful tool which provides a universal language with which to reason about any subject matter.

Sources of Authority

The sources of authority in predicate logic are the peer-reviewed papers published in journals and conferences, where new results are proved in a rigorous mathematical manner. Among the many prominent logicians, Kurt Gödel (1906–1978) and Alfred Tarski (1901–1983) can be singled out as two of the most influential and important of all time: neither created this subdiscipline, but they both changed it profoundly and set forth research in new and unexpected directions (Gödel 1986; Tarski 1983).

Ethical Principles

Since predicate logic has no direct effect and is not affected by the physical world, ethical or moral considerations have no especial application here. Being honest, as in any scientific discipline, would be the main guiding principle.

Key Values

It provides an abstract framework in which to reason in a precise manner about any subject and, especially, about mathematics, for which it offers a way of attacking many interesting problems (Simpson 2000). It is a potent tool to avoid ambiguities when posing an argument as well as when solving it.

Conceptualization

Nature/World

The empirical world is of no concern to predicate logic due to its formal character. Thus, there is no explicit treatment of these terms within this subdiscipline.

Human Being

Again, this concept is not part of the field of study of predicate logic and thus the human being is not defined within this subdiscipline.

Life and Death

By the same reason, questions about life and death do not apply to this subdiscipline.

Reality

As a formal science predicate logic is not directly concerned with reality. At most, it can be said that predicate logic's principles of inference are not arbitrary but inspired on "what happens in reality," as in the case of the principle of identity (A is A) or noncontradiction (it cannot be the case that both A and not A).

Knowledge

Reasoning about knowledge is more suited for other subdisciplines of logic such as modal logic. Though not concerned with knowledge, the renowned Gödel's (first) incompleteness theorem has been widely put to philosophical uses with regard the limitations of what can be known. Roughly, this theorem states that given a set of axioms for a sufficiently strong (mathematical) system, there is always a sentence such that neither it nor its negation can be derived from the axioms using the proof theory; this implies that there are truths in the system for which no proof can be found.

Truth

Truth as an absolute notion was abandoned by logicians during the first thirty years of the twentieth century. A predicate logic sentence on its own is, in general, neither true nor false but requires a context, a given structure with respect to which it does have a truth value. Moreover, the completeness of predicate logic allows to deal with this semantic notion in a mechanical way: logically valid sentences, those which are true with respect to every structure, are exactly those that can be derived by means of the rules in the proof theory. (Different logics may use different classes of structures, so that logically valid sentences may vary from one to another.)

Note that this is in sharp contrast with truth in concrete mathematical systems where, by the incompleteness theorem, there are true sentences which are not provable.

Perception

Predicate logic is not concerned with perception since it does not have to deal with sensorial experiences.

Time

Time is not treated explicitly within this subdiscipline. Even though time could be formalized so as to reason about facts that take it into account, there are many variants of temporal logic more suited for this purpose (Gabbay and Guentner 2001).

Consciousness

Consciousness is not treated within this subdiscipline.

Rationality/Reason

Predicate logic does not define what reason is nor treats it. However, as a formal science it is driven by rationality alone, with complete disregard of the physical world.

Mystery

Mystery has no place in this subdiscipline. On the contrary, predicate logic has played an enlightening role in the clarification of the nature of many semantic paradoxes in the natural language through their rephrasing as logical sentences.

Relevant Themes

A critical issue, already sketched in the previous sections, is the notion of proof and the distinction between true and provable sentences. In particular, the results by Gödel and Tarski show that the notion of provability in a given system is definable within the system itself (assuming minimum requirements about its expressive power), whereas the corresponding notion of truth can only be defined in another system that adequately extends the original.

Logos

Andrea Hollingsworth
Department of Religion and Philosophy, Berry
College, Mount Berry, GA, USA

A Greek word meaning reason, word, or message. In ancient Stoic thought, Logos referred to the ordering principle of the cosmos. In the Greek Old Testament wisdom literature, it referenced the wisdom of God, sometimes personified in

feminine form (Prov. 8:1–36; Wis. 7:22–30; Wis. 9:1–2). New Testament writer John, drawing on Hellenistic and/or Hebrew thought, presented Christ as the *Logos* through whom all things were made, in whom dwelt the life of humanity, and who became flesh and made a dwelling among us (Jn. 1:1–14).

The dimension of human life known as love seems unique. In fact, theologians have occasionally proposed that in order to balance out the overemphasis on the capacity for abstract thought in defining humanity, the capacity for love should be underlined instead. As it is, though, affectual bonding between parents and their offspring or an individual and a particular sexual partner is seen in many taxa of birds and mammals. Hence, when it comes to love, humans are clearly not alone. Based upon the terminology used in Ancient Greek texts, one should distinguish between at least four types of love: the ► [romantic](#) and sexual *erōs*, the friendship oriented *philia*, the parental *storgē*, and the selfless, forgiving *agapē*. Of these, the present entry concerns only the first.

As Andreas Bartels and Semir Zeki comment, romantic love, celebrated throughout the ages as perhaps the most overwhelming of all affective states, has been the inspiration for some of the

loftiest achievements of mankind. Characteristically directed toward a single person, it is a complex sentiment involving cognitive, emotional, and behavioral components. Any study of it is thus a study of a phenomenon with a myriad of components, some of which (e.g., the erotic aspect) can also act independently of the others. The converse, however, is not true – all the noted components constitute essential ingredients of love (Bartels and Zeki 2000, p. 3829). As Carl Gustav Jung points out, studying love is further complicated because love reaches into every aspect of human life. It may be studied from ethical, social, psychological, philosophical, aesthetic, religious, medical, legal and other standpoints. But above all love is still an intensely *individual* experience which means that all generalizations about it – be they scientific or otherwise – are rough approximations at best (in the same way, religious beliefs – although constantly codified in the course of history – are always an individual experience which bows to no general rule) (Jung 2008, p. 27f).

According to Barry Komisaruk and Beverly Whipple, the word *love* derives etymologically from “desire,” “yearning,” and “satisfaction,” sharing a common root with “libido.” These authors define love as *one’s having stimulation one desires*. The nature of the stimulation may range from abstract cognitive (as in romantic fantasies) to direct sensory (as during sexual activities). Thus, love encompasses having a bond with someone for whom one yearns as well as stimulating one’s desires (Komisaruk and Whipple 1998, p. 927). The strength of this definition is that it is applicable also to nonhuman species (important in tracing the evolutionary origins of love) and directly points at the *motivational* quality of love in relation to reproduction (see below). Its weak spot is the emphasis on sexual desire. As Helen Fisher and colleagues point out, the existing studies of romantic love routinely conflate ► [the sex drive](#) with love’s motivational system. Yet it is well known that the sex drive and courtship attraction depend on different neurochemical systems (Fisher et al. 2006, p. 2174). This is an apt remark because even though one may use the phrase *to make*

love interchangeably with *to have sex*, most adults know from firsthand experience that having sex has often very little to do with love. Hence, for a mature scientific approach to love, more structured models are needed.

One of the ways to clarify the issue is to start from the evolutionary *origins* of love. From this perspective, love represents an “end solution” in developments relating to the concern for survival. This “solution” is manifested in various responses that involve transcending self-oriented behavior. It is impossible for an organism to exist completely through itself; its well-being and identity do not depend on internal relations only but also on the relation to otherness (Kather 2008, p. 27). Hence the evolutionary background for motivational states that promote non-self-oriented behavior and communication. This might, perhaps, be called the transcendent function of love.

In good accordance with the foregoing, it has been proposed that love should be viewed in terms of motivational complexes rather than emotions. Fisher and colleagues define emotions as affective states of *feeling*; motivational complexes are systems related to the pursuit of a specific *want*. In this sense, romantic love is not primarily an emotion. Love is not associated with a distinct facial expression as are primary emotions. Unlike emotions, love is focused on a *specific* reward - a specific individual. Rather, love is a motivation system designed to build and maintain an intimate relationship with a preferred partner. In fact, romantic love may be considered a fundamental *drive* distinct from the sex drive: love motivates an organism to pursue a *preferred* mating partner (note – the sex drive is aimed at seeking copulation with a *range* of partners). Unlike the sex drive which is often temporarily quelled when satisfied, love does not decrease with coitus, persisting for months; also, one can be in love with someone with whom one has had no physical or sexual contact. The sex drive is mediated via androgens and estrogens. Individuals with higher levels of testosterone (T) engage in sexual activities more frequently; women show more sexual interest around ovulation when the T levels are higher than at other times.

Romantic love, however, does not linearly depend on gonadal hormones – taking T in order to boost sexual interest does not cause one to fall in love (Fisher et al. 2006, pp. 2176f, 2181). In fact, romantic love seems to result in untypical changes in T-to-E (E standing for estrogens) ratios. The concentrations of T (relative to E) vary in opposite directions in the two sexes ($T > E$ in males, $E > T$ in females). Intriguingly, men in love demonstrate decreasing T levels, but women produce more T (Esch and Stefano 2005, p. 184). It is as if in love, males come hormonally closer to females and vice versa. Theoretically, these changes should at least in males reduce libido.

The motivational complex we know as love, thus, does not coincide with the sex drive: they are associated with interrelated but distinguishable neural networks. This statement can be approached on several levels. First of all, in nonhuman species, one can observe what Fisher and colleagues call the *courtship attraction system*. Courtship attraction is characterized in mammals by increased energy, focused attention, obsessive following, affiliative gestures, possessive mate guarding, and motivation to win a preferred mating partner (Fisher et al. 2006, pp. 2173f, 2181). These features are so obviously similar to human behavior during intense romantic love that the evolutionary linkage between the two seems clear. That, however, is not all. As noted above, romantic love is a derivative of parent-offspring bonding. The evidence for this is that even though there are courtship attraction systems in fish, amphibians and reptiles, these taxa do not seem to have any affectual bonds between individuals. Affectual bonding with a sexual partner thus seems to have originated from the parent-offspring bonding characteristic of birds and mammals. Among other aspects, these links deserve an emphasis because in humanities love has often been thought of as a purely cultural construct. It is not difficult to show that our current Western concept of romantic love is historically recent. Moreover, different cultures have different understandings of love. And cultural ambience strongly influences an individual's experience of love. However, the

physiological substrate of love goes back to pre-human species. Therefore, no matter how different the particular concepts of romantic love may be in different societies, they are still just variations on the same main theme. Biology influences culture and vice versa.

Thanks to the continuity of human romantic love with its prehuman prototypes it is not surprising that romantic love is a cross-cultural universal – Fisher and colleagues refer to a survey of 166 societies of which evidence for romantic love was found in 147; there were no negative data – in the remaining 19 cultures anthropologists had failed to ask the appropriate questions, all were cases of ethnographic oversight (Fisher et al. 2006, p. 2175). Some authors have interpreted this universality quite boldly. Jonathan Lear, for example, reconceptualizing the Freudian doctrine of libido, argues that love is a *basic natural force* (Lear 1990, p. 181). Jung has likened love to a “force of destiny” (Jung 2008, p. 27). As Fisher and colleagues put it, romantic love begins as an individual starts to regard another individual as *special* and *unique*. The beloved’s worthy traits are aggrandized and the flaws minimized. The lover feels energized and ecstatic when near the beloved (this is expressed via a host of sympathetic nervous system reactions such as sweating, heart pounding, etc.) and suffers separation anxiety when apart from the beloved. The lover is emotionally dependent upon and exhibits empathy (to the point of self-sacrifice) and sexual desire for the beloved as well as intense sexual possessiveness. However, the lover’s craving for *emotional* union supersedes her/his craving for sexual union with the beloved. Most characteristically, the lover *thinks obsessively* about the beloved. Romantic love is involuntary, difficult to control, and generally impermanent – in humans, it typically lasts from 6 months to 3 years (Fisher et al. 2006, p. 2174f).

The ecstatic feelings associated with romantic love are the result of the release of dopamine, norepinephrine, and serotonin. The latter combination has a pleasure-evoking effect which is quite similar on the brain level to that of the amphetamines (Fisher 2004). There are two

brain areas that reliably display love-specific activation: the ventral tegmental area (part of the brain’s reward system) and the caudate nucleus (mediates reward expectation). Cortically, neural activity associated with romantic love concentrates in the main areas of the middle insula and the anterior cingulate cortex. Other structures activated are the hippocampus, putamen, and cerebellum. Task-specific deactivations relate to the right prefrontal, parietal and middle temporal cortices, the posterior cingulate gyrus, medial prefrontal areas, and the posterior amygdaloid region (Fisher et al. 2006, p. 2175f; Bartels and Zeki 2000, p. 3831).

Bartels and Zeki have also studied the parallels and differences in the neural correlates of romantic vs. maternal love. They have discovered that several activated regions overlap precisely, including those in the striatum (putamen, caudate, and others), insula, and the anterior cingulate cortex. The most intriguing difference between the two varieties of interpersonal love is that the hypothalamus activates during romantic love but shows no change in maternal love. This is in accordance with the proposition that romantic love ought to be thought of as a motivational complex rather than a primary emotion: the evolutionarily ancient hypothalamus, forming the key link between the autonomic nervous system or ANS, the brain, and the endocrine system, is the main generator of basic motivational states (such as thirst, hunger, and sexual desire). Romantic love also specifically activates the hippocampus. Activity specific to maternal love concentrates to the lateral orbitofrontal cortex and the periaqueductal gray (Bartels and Zeki 2004, p. 1161). Thus, maternal and romantic love should not be played out against one another. They represent motivationally different variations of the same basic pattern.

From a certain perspective, romantic love may be viewed as a transitional state between everyday, baseline consciousness and altered states of consciousness such as intense religious and mystical experiences (d’Aquili and Newberg 2000, p. 43). Given the transcendent aspects of (romantic) love, it is no coincidence that from times immemorial people have perceived

of a link between love and religion. As Jung put it, “Love has more than one thing in common with religious faith. It demands unconditional trust and expects absolute surrender.” (Jung 2008, p. 44)

Love (Alterity, Relationship)

Cristobal Solares

Antoniano University, Rome, Italy

Love constitutes a central issue in every human life. Furthermore, persons can only understand their own self through the perception of others, through “otherness.” The overwhelming psychological evidence points to the role of the mother as a condition to the child’s awakening to self-awareness, an experience of being loved which is condition to further extend the ability to love others. The received love is a precondition to love-giving. Such a dynamic reveals a close link between love, relationship, and otherness.

Otherness or alterity refers to the reality of other person, to the difference he/she makes, and his/her insurmountable diversity. The access to the other calls for a special kind of relationship, of respect and communication, different from the relation with other things and beings.

A philosophical distinction reveals three different ways to understand love: distant love, instant love, and constant love. It corresponds to a treatment of the other as an object, as a person, and as a “neighbor.” After humanism has grown during the Enlightenment, with its characteristic individualism and solipsism, a crisis arises since the second half of the twentieth century becomes more aware of the negative consequences of this anthropologic model, prompting a critical awareness in philosophy, psychology, social sciences, and literature. Only overcoming the individualistic pattern would be possible to avoid the catastrophes witnessed in the last century.

Philosophers and anthropologists of Hebrew and Christian inspiration (F. Rosenzweig, M. Buber, E. Lévinas, G. Marcel, F. Ebner, P. Ricoeur) have outlined the dimension of love focusing on otherness, on the ability to overcome a self-centered view and welcome the presence of the other as a gift, revelation, and ethical calling. This approach has been paramount to all the efforts to overcome the abuses linked to an

objectivation of the other and to its manipulation and every kind of abuses.

M. Buber and E. Lévinas have elaborated a radical philosophy which recognizes absolute primacy to the other and deduced the ethical consequences of such a new perception (Buber 1962; Lévinas 1999). Part of the contemporary psychology has evolved into this new paradigm, trying to discern the healthy and the pathological elements which arise from this way of understanding relationships and love (Kernberg 1995).

An anthropology that points to the centrality of otherness in the constitution of the self has long-standing effects in the dialogue between science and theology. From a side, this model could be understood as a bridge trying to link both disciplines around a kind of “normative common ground” (Entralgo 1988). On the other hand, the weight recognized to otherness can mean a blow to several scientific anthropologies, especially those of biological foundation, as it subverts the dogma of self-interest guiding such views. Theology is called to a reelaboration of

key concepts to make place to this new view of other-centered self. In any case, the concept of love, as a disposition opening and orienting to others, should be welcomed as a healthy complement to more individualistic standard views, both in science and theology.

Magic

Sørensen Jesper
Institute of Culture and Society, Århus C,
Denmark

Related Terms

[Anthropology](#); [Mental process](#)

Magic has been and is likely to continue to be a contested concept in disciplines such as the study of religion, anthropology, sociology, and to a lesser extent history. Caught in a negative relation to the, usually, positive valued concepts of “religion” and “science,” magic has all too often functioned as a dustbin category used to designate ritual practices that did not fit into prevalent definitions of religion or to attempts to manipulate the world that did not fit into current definitions of science. Further the concept has

a troubled history functioning as polemical ammunition used to denigrate competing ritual practices (e.g., Protestant polemics against Roman Catholic understandings of the Eucharist as “hocus pocus”), and as an integrated part of ideological primitivism, according to which “their” (primitive) rituals are magical, whereas “our” (civilized) rituals are religious. This has led several scholars to argue that the concept is best abandoned from scientific discourse. This, however, is premature for several reasons. A troubled past is a problematic reason to abandon concepts as this potentially could lead to a cascade of other concepts also having to be abandoned for similar reasons. Most general concepts in the study of religion and anthropology have a problematic history and most have been used for politically dubious purposes and outright polemics. Abandoning such concepts might deplete the disciplines of useful conceptual tools. Further, a troubled past does not necessarily mean that the concept does not circumscribe a class of real world phenomena. Therefore, a more sound strategy would be to redefine magic as a scientific concept in much the same vein as concepts such as myth, ritual, and even religion have been more or less successfully redefined in the study of religion and neighboring disciplines during the last four to five decades. That being said, it is also evident that such a definition of magic will not be based on necessary and sufficient condition but, rather, will delineate a number of core features that show a high probability of coexistence and, perhaps, causal interdependency. Magic does not

refer to a natural kind but to a number of cultural and social practices unified by family resemblance. As such, like myth, ritual, and religion, magic is a synthetic category that circumscribes a number of features, each of which must be explained before attempting a more thorough investigation of the synergetic or functional effects. A more serious challenge to the viability of the concept would be that it does not delineate any real world phenomena – that it is a mirage of scholarly imagination. There is, however, no reason to believe that the phenomena traditionally circumscribed by the concept of magic will disappear together with the concept – people are still likely to pierce dolls with needles, burn the hair of their enemies, and ingest substances believed to contain desirable essences. Finally, even though the concept has been criticized, few scholars have been able to come up with viable alternative concepts and most have instead continued using the concept, even with some reservations. However, asking for a direct correspondence between a concept and phenomena in the world seriously disregards the established model-dependency of all human concepts: Concepts are related to mental and/or public models that to some extent fit the world by eliciting certain aspects of reality relevant to humans. As such, they will never correspond *in toto* to any real world phenomena, even though the degree that this is the case depends on the kind of phenomena designated as well as the type of concept employed. Natural kind concepts (such as “dog”) are thus able to elicit a larger degree of correspondence than social kind concepts (such as “family”), but in both cases, the relation is mediated by cognitive and social models highlighting some and not other aspects. In the case of second-order scientific concepts, these models should be made explicit, founded in theories and related to theoretical models of relevant neighboring concepts as well as to relevant higher and lower level scientific theories. Thus, magic should be relegated to its proper position as a synthetic concept that designates a range of potentially interrelated phenomena each of which are susceptible to scientific investigation. In order to arrive at such an understanding, however, we need to look at

(1) the history of the concept; (2) different scientific approaches; and (3) recent cognitive investigations of underlying mental processes.

Conceptual history: The concept of magic has a long history in European languages, even if its diffusion and actual use was severely limited until the Renaissance and the later emergence of the modern science of anthropology. As a cognate of the IE *magh* (to be able, to have power), the modern form has its origin in the Greek *mageia* (the arts of the *magos*) and more particular in *magos*, a word allegedly designating ritual specialist of Persian or Median origin. As such, it designates ritual specialists of a foreign origin in contrast to local cult. There is, however, no indication that these practices were considered less efficacious or morally dubious. As a more abstract concept, magic was employed to distinguish medical treatment from ritual counterparts in the emerging Hippocratic medicine. Epilepsy, generally considered to be a disease indicating divine intervention (*The sacred disease*) calling for ritual treatment, was reclassified as a physical disease in need of medical treatment by Hippocratic writers in the late fifth or early fourth century BCE. Thus, early on, we find two of the characteristics later used to define magic: (a) a ritual practice of foreign or exotic origin (b) aimed to produce a stipulated effect. As such these practices could be seen as competing with both established ritual practice as well as with emerging “scientific” technologies based on a non-ritual, instrumental, and, partly, material understanding of the world (Lloyd 1979). Whereas the dichotomy to science receded to the background during the Middle Ages only to be reinvigorated in the Renaissance, its opposition to established religion was vividly endorsed in the Middle Ages. Exemplified by the New Testament figure Simon Magus, magic referred to ritual power made for monetary purposes in contrast to the morally superior miracles performed by the apostles (Acta 8,5–24). Thus, another distinction was introduced – that between miracles and magic. Whereas the former result from or are related to legitimate rituals, involve the direct intervention of a deity, and are made for morally superior reasons, the latter was

understood as a class of illegitimate rituals not needing the intervention of deities (or even forcing these) to be effective, and made for morally dubious and often monetary reasons. The distinction between “our” legitimate and moral rituals and “their” illegitimate and immoral rituals can also be found in both Jewish and Muslim rhetoric and magic has this conceptual function during most of the Middle Ages. This distinction might be thought of as a result of attempts by monotheistic (or monolatric) religious authorities to establish an institutional hegemony, thereby excluding competing ritual practices. Such polemics of legitimacy and authority indicate, however, that non-authorized ritual performance was indeed widespread and that institutional control over ritual behavior was hard if not impossible to achieve. Further, competing ritual practices were often incorporated into the official cult and, as such, the concept’s polemical aspects should be seen in a wider context of ritual competition, institutional dynamics of rationalization, and routinization, as well as contrast between ritual practices of an urban elite and those of the rural population.

The polemical aspects of magic as a concept were further emphasized in the Renaissance due to two independent factors. First, the emergence of diverse forms of Protestant Christianity entailed that magic became part of the newly emerging demarcation between “right” and “wrong” interpretations of central Christian rituals and dogmas. Magic thus came to designate not only ritual practices outside mainstream tradition (whether Jewish, Christian, or Muslim), but also a particular ritual attitude, i.e., the belief in automatic ritual efficacy. This was most obvious in the cases of Protestant polemics against Catholic interpretations of the Eucharist, in particular the dogma of ritual efficacy based on *ex opere operato*, but this was generalized into a conception of magical rituals as based on automatic efficacy in contrast to religious rituals that involved the intermediary intervention of a god or another types of superhuman agent. Second, magic came to designate a range of special intellectual and technical endeavors in the renaissance based on ideas of micro-macrocosmic

correspondences, astrology, alchemy, kabbalah, and hermeticism. Encouraged by the resurgence of neo-platonism, renewed interest in non-Christian philosophy and theology, and the decline of the Middle Age distinction between the celestial and earthly spheres, circles within the intellectual elite attempted to expand human mastery of its surroundings by means of a range of techniques including “natural magic” (Yates 1964). Correspondences between the human body, nature, and the celestial spheres enabled the renaissance magus to predict future events and to manipulate both the human body and nature, exemplified by the alchemical search for the philosopher’s stone. Renaissance magic thus combined notions of a reanimated universe, containing numerous forces that could be manipulated by the knowledgeable, with a reevaluation of magic, epitomized by references to the “wise kings of Matthew” of the New Testament and their prediction of the birth of Jesus by means of astrology. Renaissance magic was thus intimately connected to the emerging sciences and its ideas of lawfulness of nature – in fact most scientific pioneers such as Kepler, Brahe, and Newton had strong interests in astrology and alchemy – and this connection was not severed before the Enlightenment.

Scientific approaches: In summary, a semantic cluster can be discerned through this short historical survey of the meaning of the concept of magic: Magic was considered in opposition to both religion and science; it was believed to be directed toward instrumental efficacy based on lawfulness of nature; it was efficacious but immoral and heathen ritual; it was the ritual of the Other; and its efficacy was more or less automatic rather than mediated by a superhuman agent. Early anthropology and science of religion inherited this understanding of magic, even if different schools have put its emphasis on different aspects. Three major approaches can be discerned in the first 100 years of scholarship. First, Victorian anthropologists understood magic in the framework of a general evolutionism and in what was later called an intellectualist approach. Intellectualists understood the phenomena of magic, religion, and science in terms

of individual mental processes aimed to explain and control aspects of the environment. Combined with the gradualist evolutionism and progressivism prevalent of the late nineteenth century, magic was explained as the attempt by primitive humans to control the environment through essentially rational but futile actions. Inspired by empiricist ideas of human reasoning, James Frazer (1854–1941), undoubtedly the most famous Victorian theorist of magic and religion, argued that magic rests on the misapplication of two ordinary mental operations: association by means of prior contact, and association by means of similarity. Primitive humans mistake such ideal associations for real connections, leading to the two basic principles of magical actions: contagious and homeopathic magic. Using these principles, people attempt to control their environment by means of associative relations, e.g., throwing water into the air in order to attract rain or hurting an enemy by burning something that used to belong to him or her, such as hair, nails, or clothing. These manipulations are believed to have an automatic efficacy as they build upon a sensed (but ultimately flawed) appreciation of natural lawfulness, and therefore, Frazer could describe magic as the “bastard sister of science.” He believed that sooner or later, people would recognize the futility of magical attempts to control the environment and, instead, see the contingency of events to be the result of an active but invisible agent, a god, spirit, or ancestor, thereby heralding the age of religion that would, eventually, itself be supplanted by modern science (Frazer 1922). In Frazer’s view, all humans, past and present, can be positioned on this unilinear evolutionary trajectory, enabling the scholar to understand modern “primitives” as a contemporary image of the Western Europeans’ own cultural past and, *vis versa*, understand past cultures through the lens of modern-day “primitives.” Nobody today accepts such a simple evolutionary schema, but Frazer’s two principles of magic still form a basic, if somewhat dated, conceptual bedrock to scientific investigations into magical rituals. Thus, two ideas should be extracted from the intellectualist approach, which have a continued importance in the contemporary

study of magic – the focus on the underlying mental processes in magical rituals and the instrumental purpose of the rituals involved.

The second approach is symbolist. It rejects the understanding of magic as being primarily directed toward the manipulation of the environment in favor of the view that magic is a type of ritual behavior distinct from ordinary instrumental action and that it therefore is primarily expressive and symbolic, i.e., consisting of signs that point to something else. Symbolists tend to disagree about what the symbols point to and what methods should be used to decipher the symbols. Thus, different theories have been presented from Freudian unconscious feelings of omnipotence and schizophrenia to central values and structures of society. Prominent among the symbolists was the French sociological *Annale* school represented by figures such as Émile Durkheim, Marcel Mauss, and Henri Hubert. Rejecting that a universal phenomenon such as religion can be explained in terms of mistaken mental operations, Durkheim (1858–1917) famously linked the emergence and stability of human society to religion through the process of a ritual celebration of Society in the form of a totemic emblem. Accordingly, magic was understood as derived from religion – in fact as its antisocial mirror image in which sacred objects are used for private purposes. Whereas religions form a church and thus are eminently social, magicians have clients that buy ritual favors in exchange of some material payment and as such magic is rightly scorned by religion because it works for the benefit of the individual in contrast to the encompassing social effervescence of religion (Durkheim 1912). Even if not all symbolists agree with this negative assessment, all agree in pointing to a hermeneutic method in order to extract the underlying and implicit meaning and function of explicit magical performance. Disregarding the purported instrumental aspects of magic, symbolists instead understand magic as symbolic, and the symbols must be deciphered by means of an interpretational “key.” This raises two problems. First, magic must be distinguished from other types of behavior and second, one must somehow make the chosen interpretational key plausible by

reference to an overarching theory. The first problem was solved by pointing to the obvious ritual aspect of magic – an aspect disregarded by intellectualist in their understanding of magic as a mistaken but instrumental and rational behavior. The second problem is trickier as the choice of overarching theory is hard to justify by reference to the subject matter under investigation without ending up in a circular argument. Thus, by grounding the inherited distinction between magic and religion in its social function and not in any overt characteristics, symbolist designation of some practices as magic often ended being based in local polemics between established and less established ritual traditions, or between institutionalized and noninstitutionalized ritual practices. Recognizing this problem led many scholars to argue that the concept is best abandoned, as magic seems impossible to distinguish from religion from an etic perspective. Even if this consequence is rejected here, for reasons that should be apparent below, symbolist accounts have pointed to two important aspects. First, that magic is best understood as a type of ritual behavior and second that magic employ established symbolic relations in order to enact particular types of ritual manipulations.

The third scholarly approach is pragmatic and performative. Championed by the Polish-British anthropologist Bronislaw Malinowski (1884–1942). Pragmatists focus on the pragmatic and performative embedding of concrete rituals and they are generally less interested in magic *per se* as in how its performance accomplishes particular social and psychological tasks. Having said that, most uphold the distinction between magic and religion due to function and scope. Malinowski, for instance, argued that both magic and religion have the primary function of ensuring the stability in social institutions by acting directly on the emotional well-being of the individual. In short, religion appropriates the inevitable life-crises, relates them to basic mythic structures and thereby alleviates emotional distress, and confirms institutional authority and belief in Providence. As such, religion works in the long perspective, as no direct instrumental effect is represented in relation to its rituals. In

contrast, magic works in the short perspective. It aims to alleviate anxiety related to particular pragmatic endeavors that are imbued with high degrees of uncertainty. Magical rituals thus install a sense of security in participants and thereby ensure that uncertain but vital actions, such as those related to agriculture, are performed. Therefore, magical rituals are closely intertwined with pragmatic actions such as fishing or planting a garden, but Malinowski emphatically denied that participants fail to distinguish between ordinary instrumental actions informed by common sense causal principles, and magical actions informed by traditional authority. Even if the latter are conceived as instrumental, their instrumentality derives from the performative aspects of ritual magic. In line with later performative approaches to language, Malinowski emphasized how language in practice effects a change in behavior rather than refers to or describes some aspects of reality. Adopting this view to ritual, he pointed out that ritual performance could effect a change in, for instance, social status (e.g., through a wedding ritual) and that this change is produced by particular words being uttered by the right person. There is only a short step to allocate the same performative power to rituals aimed to change aspects of the environment other than social status. Accordingly, magical rituals are understood as powerful due to ordinary experience of words being able to alter social reality (Malinowski 1948). Three aspects should be extracted from the performative approach: First, magical rituals are intimately related to non-ritual pragmatic endeavors, even if participants have a clear understanding of the difference between instrumental and ritual behaviors. Second, magical rituals manipulate the emotions of participants and as such have a direct effect on human behavior. Third, representations of ritual efficacy is, at least partly, a product of the performative aspects of ritual language as well as the conceived authority of the agents performing central parts of the ritual sequence.

These classical approaches to magic continued to influence anthropology and the study of religion throughout the twentieth century.

Discussions between intellectualist and symbolist approaches were particular evident in the so-called rationality debate in the late 1960s and early 1970s (Wilson 1970), whereas performative approaches gained prominence from the early 1970s (Tambiah 1990). With the rise of postmodern, poststructuralist, and postcolonial approaches, the concept of magic was, however, criticized as being an instrument of power and its polemical history was highlighted as an argument for its scholarly inappropriateness. To the extent that its use was inevitable, it was used in a rather narrow, emic way as a means to describe localized ritual practices that for some reason were considered illegitimate, socially marginalized, or part of folk religion in contrast to institutionalized religion. Thus, no universal definitions were given, a fact that made cross-cultural comparison difficult and interests turned instead toward the genealogical explorations and critical examination of the concepts history in Western scholarship (Styers 2003). At the same time, however, a growing interest of the mental processes underlying magical practices can be found in cross-cultural psychology, cognitive psychology, and evolutionary psychology as well as in cognitive linguistics. Instead of rejecting magic as a product of the researcher's imagination when engaging "the Other," these approaches seek to "normalize" magical thinking and argue that the underlying mental processes are a part of ordinary human cognition found in all societies, at all times, and in all people. Two aspects of this research should be mentioned here. First, building on a long tradition in developmental psychology pointing to the existence of magical beliefs in children, psychologists began to wonder if this indicated a more general proclivity to magical thinking among adults as well. Thus, Rozin, Nemeroff, and colleagues found mental operations similar to those described by Frazer when investigating contemporary Americans' notions of contamination and disgust. Subjects consistently reacted toward a potential transfer of undesirable essences when presented with relations solely based on contagion and similarity. Drinking from a glass that had previously been in contact with a cockroach, even if the glass was

later disinfected, was represented as able to transfer undesirable essences. Wearing a jumper claimed to have belonged to Hitler was judged to be repellent, even if dry-cleaned or reknitted. In a similar fashion, relations based on similarity were thought to transfer unwanted essences as when subjects consistently refused to drink sugar water from a glass with the sign "poison" written on it, even when having observed the sugar and water being mixed. Of particular interest was the finding that this also holds for backward causation. People felt uncomfortable if their lost hairbrush should fall into the hands of an enemy or the picture of a loved one into the hands of a despised person (Nemeroff and Rozin 2000). At this point, it is crucial to bear in mind that these findings do not entail the existence of conscious beliefs about the importance or efficacy of such sympathetic relations nor the endorsement of such beliefs, should they be there. Rather the studies are testimony to a number of cognitive systems activated by very particular perceptual cues and often when lacking other relevant types of information.

That the cognitive systems underlying magic is indeed basic and universal is also testified to by findings in cognitive linguistics. Already in the 1950s, linguist Roman Jakobson pointed to the fundamental similarity between metaphor and metonymy, on the one hand, and magic based on similarity and contagion, on the other hand. Since then, metaphor and metonymy have ceased to be considered purely stylistic features of language and are now considered to be expressions of very basic cognitive processes, underlying features such as categorization, formation of stable conceptual structures, as well as meaning construction. Our brains are apparently well suited to reason by means of conceptual relations created through relations of contact or similarity. Recent research, however, indicates that these underlying cognitive processes might be domain specific, i.e., activated by a circumscribed number of perceptual cues. Thus, contamination avoidance is a likely candidate for a specialized cognitive system due to its adaptive role in human evolution. Several of the examples mentioned above do seem to indicate

that a substantial number of magical practices are concerned with or exploit contamination fears, but whether positive contagion, i.e., appropriation of positive essence through contact or similarity, is parasitic on such an evolved contamination system or whether other systems are activated remains to be seen.

Based on these and other findings that all indicate the universal substratum of cognitive processes underlying magical behavior, the question naturally arises why connections based on similarity or contact are sometimes judged to be able to effect real world changes, whereas in other cases, and likely the majority, the same relations are regarded as inferential tools without any real world efficacy. In order to answer this question, we need to recognize that most magic is performed as an integral part of a ritual and that ritualization of action sequences effects our cognitive system in a particular way. A number of scholars have pointed to characteristics of ritualized behavior such as iteration, scriptedness, formalization, exaggeration, etc. Different theories have been proposed to account for these phenomena, but in this context, we are more concerned with the cognitive effects of these features, of which two should be mentioned. First, rituals are intentionally underspecified. In contrast to most ordinary actions, the agents performing the action usually have no saying in how the actions should be performed. Rather these are specified by tradition and often the very efficacy of ritual is described as dependent on obedience to this formal specification. Second, rituals are causally underdetermined. There are no inherent causal connections between the actions performed and any effect claimed to result from it. Rather, correct performance is generally claimed to have particular effects by reference to tradition and non-efficacy or even reverse consequences are claimed to result from failure to perform the ritual in the correct way, even if differences of opinion often exist as to the exact effect of a particular ritual, not to mention how these alleged effects are produced. These characteristics of ritualized behavior have led some scholars to understand magic as a heuristic

strategy activated in an attempt to relate ritualized actions to its immediate pragmatic context. Instead of the strong causal predictions involved in ordinary actions, in which the human cognitive system predicts particular outcomes based on domain-specific inferences, the causal underdeterminacy of ritualized behavior redirects cognitive operations toward perceptual cues that might help relate the actions performed to the immediate pragmatic context. Searching for relations of similarity, contagion, and temporal and spatial contiguities between entities is a default strategy when lacking stronger causal or intentional cues in events or actions observed, a fact that is testified by its predominance in the learning strategy of operant conditioning described by behaviorist psychology. As such, magic can be explained as pointing to a number of cultural practices that exploit particular features of human cognitive processing resulting in representations of ritual efficacy. This representation of efficacy, in turn, leads to promulgation of the ritual practices best fitted to activate such cognitive processing as they are deemed to be more relevant in relation to the performance of local pragmatic endeavors (Sørensen 2007).

In summary, it should be clear that magic is not a natural category and that it does not refer to a natural set of causally connected phenomena that can be explained by means of a single theory. Rather, the concept refers to a number of phenomena that for historical reasons are connected in a synthetic concept organized by family resemblance. Some of these phenomena *might* be causally interrelated and thus amenable to a unified explanation, whereas others have only spurious or contingent relations. A host of different theoretical approaches each directed toward explaining particular behavioral and/or social phenomena are therefore needed to further investigate the phenomena underlying the concept of magic.

Magnetoencephalography (MEG) is a noninvasive brain imaging technique that records the small magnetic fields associated with electrical activity in the brain. The same electrical brain activity leads to fluctuations of electrical potentials that can be recorded at the scalp with the related measurement technique electroencephalography (EEG) Niedermeyer (2004).

MEG provides noninvasive recordings of brain activity with good spatial resolution and very high temporal resolution (about 1 ms) Hamalainen (1993). Measurements are challenged by the small amplitude of the neuromagnetic field that is typically below 10^{-12} T. The earth magnetic field for comparison is several orders of magnitude larger (about 10^{-4} T). Consequently, MEG recordings require highly sensitive detectors and efficient attenuation of environmental magnetic background activity. State-of-the-art MEG systems are equipped with about 300 highly sensitive superconducting quantum interference devices (SQUIDS). These sensors have to be cooled with liquid helium and operate at a very low temperature of about -269 °C in the state of superconductivity Preissl (2005). The sensors are arranged in a helmet-shaped dewar and cover most of the head at a typical scalp distance of about 2 cm. The many sensors allow precise measurements of brain activity in all cortical areas.

During a typical experiment, sensory stimuli may be presented, and the participant is asked to

perform a specific task Hari (1999). Stimuli and participants' response are repeated many times (about 100 repetitions are common). Information processing in the brain is associated with the activation of neurons that is characterized by changes in their membrane potentials. The MEG signal is caused by magnetic fields that are associated with postsynaptic potentials and thus reflects fluctuations in local field potentials. Prerequisites for a measurable MEG signal are the simultaneous activation of several thousands of neurons and a preferred spatial orientation of these neurons (such that summation of the tiny individual magnetic fields increases the total magnetic field measured outside the head). The magnetic fields are recorded at high temporal resolution. The data can be used to localize the corresponding activated brain areas and track information processing noninvasively in the human brain Hari (1997), Hari (1997b), Lu (2003), Schnitzler (2005).

MEG has been used in cognitive neuroscience to study language, neural plasticity, attention, memory, consciousness, motor control, etc. In addition, detailed studies of sensory processing in primary sensory areas have been conducted using the excellent temporal resolution of MEG.

A large number of studies have used MEG to investigate pathological mechanisms in many diseases Papanicolaou (2008), Schnitzler (2005).

In general, MEG is ideal for applications that require a high temporal and good spatial resolution. Although the spatial accuracy is better for functional magnetic resonance imaging (fMRI), no other noninvasive imaging technique offers a better temporal resolution with coverage of the entire brain combined with a good spatial resolution.

Mahāyāna Buddhism/Vajrayāna Buddhism

Karim Fathi

Viadrina Europe University Frankfurt (Oder),
Berlin, Germany

Mahāyāna (“The Great Vehicle”) developed from Theravada and is found throughout East Asia. It includes the traditions of Mādhyamaka, Zen, Nichiren Buddhism, Tibetan Buddhism, Tiantai, Pure Land, and Shinnyo-en. According to the teachings of Mahāyāna traditions, “The Great Vehicle” refers to the path of seeking complete enlightenment for the benefit of all sentient

beings, also called “Bodhisattvayāna.” In contrast to Theravada, the individual achievement of bodhi (awakening) is therefore not the ultimate goal in Mahāyāna Buddhism. The Buddha nature (Sanskrit: “Tathāgatagarbha” or “Buddha dhātu”) is considered to be present in all beings, creating an immanent link to the awakening, constituting the deathless “essence of the self.” As a consequence of Mahāyāna’s nondual philosophy, any being is therefore regarded as already enlightened, whether aware of it (meaning “awakened”) or not.

Vajrayāna (often translated as “The Diamond Vehicle”) or “Tantric Buddhism” is mainly practiced in Tibet and Mongolia and recognized as a part of the third branch of Buddhism, while others classify it as a part of Mahāyāna. Vajrayāna techniques, including Dzogchen and Mahamudra, are aimed at making it possible to experience the Buddha-nature prior to full enlightenment.

Markov Process

Gómez González Daniel
Universidad Complutense De Madrid, Madrid,
Spain

In probability theory and statistics, a Markov process (the name is due to the mathematician Andrey Markov), is a time-varying random phenomenon (stochastic process) for which a specific property (the Markov property) holds. A stochastic process satisfies the Markov

property, if the probability of what is going to happen tomorrow conditioned to what is happening today is the same that the probability of what is going to happen tomorrow conditioned to what have happened previously. This property is informally known as memorylessness or non-memory property.

Marxism

Materialism

René Rosfort
Department for Systematic Theology, Faculty of
Theology, University of Copenhagen,
Copenhagen, Denmark

The view that all entities and phenomena in nature are material (as opposed to immaterial/supernatural). Materialism has played a decisive role in philosophical theories about the nature of reality since the dawn of western philosophy. In contemporary debate, the term is used to designate theories that claim all reality to be material and therefore reject the existence of immaterial things such as thought, consciousness, angels, ghosts, or gods. This rejection can be carried out in several ways. In philosophy of mind (philosophical theories about the nature and function of the human mind), the rejection is often done in one of two ways: by means of a reduction of the apparently immaterial phenomena and experience to material entities and explanations (Reductionism) or by way of a forthright elimination of such impalpable phenomena that are held to be subjective illusions (Eliminative Materialism)

Mathematics in Islam General

Jeffrey A. Oaks

Department of Mathematics and Computer Science, University of Indianapolis, Indianapolis, IN, USA

[Islamic](#); [Islamicate mathematics](#); [Medieval Arabic](#)

Description

By “Mathematics and Islam” we mean the mathematics practiced and developed in countries whose predominant religion was Islam, before the advent of Western colonialism. In time, this covers the eighth century CE down to about the nineteenth century, and in place from India to Muslim Spain. Despite the vast expanse of time and territory, mathematics in Islam can be said to constitute a continuous tradition, though one must always be aware of local conditions and influences.

The Cultural Background

By the time the Umayyad dynasty succumbed to the ‘Abbāsid revolution in the middle of the eighth century CE, the Islamic empire reached from the Atlantic coasts of North Africa and the Iberian peninsula to the Indian subcontinent. The unprecedented political expansion of the Muslim state in the preceding two centuries made the Arab conquerors masters of regions previously under the control of the civilizations of India, Persia, and Greece.

Out of this setting came, for complex social and political reasons, the Arabic translation

movement. From roughly the middle of the eighth century to the end of the tenth century the aristocracy and other wealthy groups within Muslim society provided an enormous outlay of funds for the appropriation of all practical and scientific knowledge at their disposal. Translators busied themselves rendering Indian, Sasanian, and especially Greek books into Arabic (sometimes through Syriac intermediaries), and mathematicians set down on paper the native traditions in arithmetic, algebra, and mensuration which had hitherto been communicated orally by trade groups. It was not just the mathematical sciences (arithmetic, geometry, optics, mathematical astronomy, etc.) which were sought out, but also works on geography, astrology, philosophy, medicine, agriculture, alchemy, and even falconry.

Not only did Greek works form the bulk of the material translated, but the more scientifically oriented mathematicians adopted the Greek structure of definitions, axioms, and propositions with rigorous proof, while astronomers embraced the Greek idea of geometric models of planetary motion. Even the philosophical underpinning of the mathematics derived from Greek philosophy. It is within this framework that Indian and Iranian techniques were incorporated into this new Arabic/Islamic mathematics.

Conjointly with the production of the translations, scholars wrote commentaries and criticisms of the ancient mathematics and made their own original contributions. We see this, for example, in Thābit ibn Qurra (d. 901), who translated several works of Archimedes, wrote commentaries on Euclid’s *Elements* and Ptolemy’s *Almagest*, criticized Euclid’s definition for the composition of ratios of numbers, and derived and proved new formulas for volumes of solids of revolution.

When the sources of Greek and other foreign texts finally dried up, scientists continued to produce new results in all branches of mathematics. Ibn al-Haytham, for instance, made major contributions to optics and geometry in the eleventh century, and al-Khāyyamī wrote his book on algebra near the start of the twelfth century. Other examples are the innovative work in astronomy conducted in association with the

thirteenth-century “Maragha school,” supported by the Ilkhanids in northwest Iran, and at Ulugh Beg’s madrasa and observatory in Samarqand in the first half of the fifteenth century. One important book which came out of the activities of scientists at the Maragha observatory is Naṣīr al-Dīn al-Ṭūsī’s *Memoir on Astronomy* (thirteenth century), in which he proposes non-Ptolemaic models of planetary motion. Parts of this work found its way, through an as yet unknown route, into Copernicus’ *De Revolutionibus*. In Samarqand, al-Kāshī (early fifteenth century) and other astronomers compiled a highly accurate set of astronomical tables whose influence reached from Europe to China.

Research and teaching in medieval Islam did not take place within western-style institutions. Translators and scholars were patronized by wealthy individuals mainly associated with the ruling court, though such personal compacts could be part of large-scale projects. And while later endowed institutions such as the madrasa (school) provided settings for teaching and learning, the transmission of knowledge was still regulated by individual teachers who conferred on students the authority over particular texts. And contrary to what many secondary sources claim, there is no record of any translation of Greek works at the House of Wisdom (*bayt al-ḥikma*). This library was most likely established by al-Manṣūr in the eighth century “to house both the activity and the results of translations from Persian into Arabic of Sasanian history and culture.” (Gutas 1998, pp. 58–59)

There was a general shift in the nature of the mathematics produced over the centuries, similar to the shift which occurred in Greek mathematics from the innovative and scientific work of Hellenistic times to the more reflective and practical work of late antiquity. By the early thirteenth century the “ancient sciences” began to be taught in the *madrasa* (school). Teachers molded their mathematics instruction to conform to the structure of the traditional (religious) sciences. In this way mathematics education became more widespread in the Islamic world, so instead of a few highly trained court specialists, one now sees broadly educated individuals.

This “naturalization” of mathematics is seen in the surviving texts, which in later centuries are on the whole more teaching-oriented and elementary. The regional variations characteristic of such large-scale social change make it difficult to put dates on this shift, but it appears to have occurred largely from the thirteenth to the sixteenth centuries. Nor can we expect uniform change across all branches of the mathematical sciences (Brentjes 2002, 2008). One area in which innovative work continued well into the sixteenth century is planetary astronomy. George Saliba and F. Jamil Ragep have documented the non-Ptolemaic theories of al-Qūshjī (d. 1474), al-Birjandī (d. 1525), al-Khafīrī (d. 1550), and others. Courtly patronage of the sciences was maintained by the various Islamic dynasties right down to the nineteenth century, but even there the values of the educated religious scholar appears to have replaced those of the earlier court specialist (Saliba 1994; Jamil Ragep 2001).

The majority of mathematicians working in the medieval Islamic world were Muslims. But some, especially those working during the translation period, were Christians, Jews, or even Sabian pagans. And although the dominant language was Arabic, many scientific treatises were written in Persian, Turkish, and Urdu.

Classification of the Mathematical Sciences

Medieval Arabic scholars adopted, with various modifications and refinements, the classification of the sciences from Hellenistic Greece. The core mathematical sciences include arithmetic, geometry, and mathematical astronomy. Cognate areas include astrology, optics, mechanics, trigonometry, music (harmonics), and magic squares. See the individual entries “Arithmetic and Islam,” “Algebra and Islam,” “Geometry and Islam,” “Optics and Islam,” and “Astronomy and Islam.” I will briefly address the background and nature of Islamic trigonometry.

Just as in earlier civilizations, people in Islamic countries had a need for astronomical calculation. Astronomers relied on instruments and tables founded on either Indian or Ptolemaic

planetary theory, whether they were calculating the rising time of a particular constellation in astrology, or determining crescent visibility conditions for the regulation of the Islamic calendar. Analog instruments, such as the armillary sphere, quadrant, sundial, and most importantly the astrolabe, were manufactured in large numbers. Based on Greek examples, the Arabic planispheric astrolabe utilizes stereographic projection of the hemisphere of the sky onto a disk. The instrument can be used for a variety of calculations, such as determining the altitudes of stars or planets and for telling time. Astronomers also relied on astronomical tables, or *zījes*. These typically consist of a couple hundred pages of tables of various sorts with explanatory text. The tables usually include trigonometric functions and the mean motions, equations, and latitudes of the planets (including the sun and moon). Some geography and astrology is also usually included.

The trigonometry necessary for the study of astronomy in Islam was a hybrid between Indian and Greek ideas. The Greeks worked with the chord of an arc, while the Indians computed with the sine function, or half the chord of half the arc. Muslims adopted the sine function, but with the Greek base 60 system. Typically, they worked with a circle of radius 60, so that their sine of an arc equals our $60 \sin \theta$. The Indian shadow function (our cotangent) was tabulated for use in timekeeping and was united with the sine and the other four trig functions by Abū'l-Wafā' (tenth century).

Tables of trigonometric functions are common in the many astronomical tables composed in Arabic from the eighth century on. Trigonometric identities can be used to find the sines of angles which are multiples of $2'' \cdot 3^\circ$, including 3° , $1\frac{1}{2}^\circ$, $\frac{3}{4}^\circ$, etc., but the tables require $\sin 1^\circ$. To find this value, from which $\sin 2^\circ$ and the others can be derived, astronomers relied on interpolation and iterative methods. In the fifteenth century al-Kāshī used algebra to find the $\sin 1^\circ$ by setting up a cubic equation whose root he extracted by an iterative technique.

Interpolation techniques were not only useful for $\sin 1^\circ$, but also for filling out tables to avoid the tedious job of evaluating all the values directly.

Various linear, second order, and iterative schemes were applied with great success by astronomers like Ḥabash al-Ḥāsib (ninth century), Ibn Yūnus (tenth century), and al-Bīrūnī (eleventh century). The most accurate tables were compiled under Ulugh Beg in Samarqand, ca. 1440. In his *Sultānī Zīj* sine and tangent functions were calculated in increments of $1'$, to an accuracy of five hexadecimal places, equivalent to about nine decimal places.

Plane trigonometry alone cannot handle many calculations in three-dimensional astronomy. Arabic astronomers inherited different approaches to spherical astronomy from India and Greece, and they eventually derived superior results. One Greek method is the analemma, used for solving problems in which the motion takes place in two planes. One plane is rotated into the other, so the calculations are reduced to two dimensions. The other Greek method, found in Ptolemy's *Almagest*, is the Theorem of Menelaus. This is a truly spherical result, but it is cumbersome for making calculations. In the tenth century, Abū'l-Wafā' derived the much more efficient sine law,

$$\frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}.$$

A , B , and C are the angles of the triangle on the sphere, and a , b , and c are the arcs (sides) of the triangle opposite a , b , and c (these arcs can regard as angles from the center of the sphere).

Trigonometry eventually became an object of study in its own right. The first book on trigonometry may be al-Bīrūnī's (973–1048) *Book on the Derivation of Chords in a Circle*. Later in the eleventh century al-Jayyānī produced a book on spherical trigonometry in al-Andalus, and Nasīr al-Dīn al-Ṭūsī (thirteenth century) wrote a comprehensive work on the same topic in western Persia (Van Brummelen 2009).

Self-identification

Science

There was no word in Arabic corresponding to the modern English "science." The closest word

is *'ilm*, which was given to any kind of theoretical knowledge, religious or secular. *'Ilm* (let us call it "science") was often distinguished from *ṣinā'a*, which refers to an art, craft, or trade. For example, practical mensuration such as we see in al-Khwārizmī's *Algebra* was considered to be an art, while theoretical Greek-style geometry was a science. (This distinction was not rigorously maintained, as many fields were called by both names even by the same author.) The Islamic arts and sciences informed each other throughout the medieval period. Mathematicians developed the art of algebra in scientific directions, while practitioners adopted the book of Euclid as a foundation for mensuration.

Characteristics

The mathematical sciences covered a vast portion of both practical and theoretical knowledge. One cannot pinpoint what is distinctive about a discipline which covers topics ranging from music theory to algebra to geometric models of planetary motion, and is used in cooking, tax collection, and astrology.

Relevance to Science and Religion

Contrary to what many earlier studies have proposed, there was no natural antipathy between religion and science in Islamic societies. Of course there were some scholars who objected to the study of the "foreign sciences," most notably the theologian al-Ghazālī (d. 1111). His book *Incoherence of the Philosophers* was seen by orientalist as signaling the victory of religious orthodoxy over Greek-inspired philosophy and science. But not only were mathematics and philosophy taught in Islamic lands alongside the *Qur'an* and *hadith* right down to the nineteenth century, but many of the leading scientists were also important theologians. Naṣīr al-Dīn al-Ṭūsī (d. 1274), Qāḍī ʿIzādeh al-Rūmī (fifteenth century), and al-ʿAmilī (d. 1622) come to mind.

Mathematics and religion crossed paths in different ways. One is the application of

mathematics to problems in the practice of Islam, another concerns the association of astronomy with the religiously condemned science of astrology, and still another is the religious objection to physical and philosophical foundations of mathematical astronomy.

Three problems in the practice of the Islamic religion attracted the attention of astronomers: (1) to determine the times of the five daily prayers, (2) to find the *qibla*, or the direction to Mecca from one's location, and (3) to know the conditions under which one can first see the crescent moon, which signals the beginning of the month (David 1993). There were two different approaches to these problems, one based on Arabic folk astronomy and the other on mathematical astronomy. In pre-Islamic times the Arabs had a good knowledge of the motions of the sun, moon, and the stars, but without any theory or calculation. Their folk astronomy was shared by cultures extending at least from India to Europe, and became the foundation on which religious scholars provided approximate answers to the three questions. With the development of mathematical astronomy Muslims found themselves equipped to answer these questions precisely. The numerous treatises devoted to the three problems were not initiated because of any need within Islamic society for precise solutions, but rather because the problems are interesting in themselves, and they provided a way for astronomers to legitimize their science.

The five daily prayers are to be performed within these specified intervals:

1. Between sunset and nightfall
2. Beginning at nightfall and lasting until one third or one half of the night has passed
3. Between daybreak and sunrise
4. Beginning when the shadow of a gnomon is observed to lengthen just after midday, and until the time of the fifth prayer begins
5. Beginning when the length of the shadow of a gnomon is the length of the gnomon greater than its midday minimum, and ending at sunset

Prior to the thirteenth century the *muezzin* regulated prayer times by the methods of folk astronomy, without instruments or tables. In the

thirteenth century we see the emergence of the new office of timekeeper (*muwaqqit*). This astronomer was usually associated with a mosque, and many who held the office compiled astronomical tables, built sundials on the principles of conic sections, and even developed models of planetary motion. Ibn al-Shāṭir, the fourteenth century timekeeper of the Umayyad mosque in Damascus, did all three.

Muslims are instructed to pray toward the *kaaba* in Mecca. This sacred direction is called the *qibla*, and early Muslims adopted a variety of methods for finding it. Some based it on wind direction or folk astronomy. Still others prayed due south no matter what their location, because that was the direction the Prophet prayed while in Medina. In Cairo alone at least seven *qibla* schemes were used to orient mosques by the fifteenth century, which varied by 114 degrees!

Astronomers calculated the *qibla* as an angle from the meridian knowing the latitudes of Mecca and of one's location, and the difference in longitude between the two points. Already, in the ninth century astronomers had found an exact (and complicated) formula as well as easier, approximate solutions. The only impediment to determining the *qibla* for a given location lay in obtaining accurate coordinates. The longitudinal difference was particularly difficult to determine.

Many *qibla* tables were compiled over the centuries, and some ingenious instruments were constructed for the purpose as well. But even confronted with the astronomers' calculations, the judges responsible for the orientation of mosques would typically choose a traditional direction to Mecca.

To predict the day the new crescent moon will become visible above the western horizon at sunset is a problem with many parameters. One must take into account that the moon and sun do not orbit in the same plane or travel across the sky with constant velocity, and that both will set at angles which vary with the seasons and with latitude. Astronomers tackled the problem based on planetary models, and they produced many sophisticated tables.

There was one application of arithmetic to Islam. The rules for the division of estates

outlined in the holy writings can be complex, so a sound understanding of arithmetical problem-solving is necessary to evaluate many cases. Al-Khwārizmī and some later mathematicians promoted algebra as a tool for calculating the shares of an estate. But some, like Ibn Khaldūn (fourteenth century), insisted that cases difficult enough to require algebra were rare.

There were two aspects of astronomy which were regarded at best with suspicion by religious authorities. One is astrology, which attributed powers to the stars which should be reserved for God, and the other concerns the physical and metaphysical foundations of mathematical astronomy. Astronomy and astrology were integrated in the astral sciences of Greece, Sasanian, Persia, and India, and the close ties between the two were inherited by early Muslim astronomers. Astrology was always popular with ruling Islamic courts, thus providing many astronomers with a steady source of income. But not only was there a conflict with religion, many astronomers did not believe that astrology was a valid science. For these reasons, beginning with Ibn Sina (d. 1037), astrology came to be treated as a branch of physics, while astronomy retained its status as a purely mathematical discipline.

Astronomers in medieval Islam continued the debate which already existed in Greek antiquity regarding the place of physics in astronomy. They also came under fire from theologians for their occasional assertion of Aristotelian natural causation. Al-Ghazālī and others generally accepted the mathematical part of astronomy, but rejected its physical underpinnings. This led astronomers to look for ways to free astronomy from physics. While some astronomers insisted that we need physics to establish a stationary earth, others believed this could be established by mathematics. Al-Qūshjī (d. 1474) was even able to dispense with physics by admitting the possibility of a rotating earth (Jamil Ragep 2001).

Sources of Authority

The writings of well over a thousand mathematicians from Islamic civilization survive, about half

of whom worked before the fifteenth century. I list below in chronological order a few of the authors whose works were highly regarded both in their own times and by historians today.

- Al-Khwārizmī (Muḥammad ibn Mūsā al-Khwārizmī). Mathematician and astronomer, worked in the first half of the ninth century in Baghdad. Composed books on practical arithmetic, algebra, astronomical tables, and wrote an astrological history.
- Ḥabash al-Ḥāsib. Worked in Baghdad, ninth century. Astronomer noted for his contributions to trigonometry.
- The Banū Mūsā. The three “sons of Mūsā,” Muḥammad, Aḥmad, and al-Ḥasan, worked in Baghdad, ninth century. Their main interests were geometry, optics, astronomy, and mechanics.
- Al-Kindī. Ninth century, Baghdad. This very important philosopher wrote several treatises on mathematics.
- Thābit ibn Qurra. Polymath from Ḥarrān and Pagan star-worshiper who worked in Baghdad, d. 901. Translated many Greek books and did original work in number theory, geometry, astronomy, and mechanics.
- Qusṭā ibn Lūqā. d. ca. 910. Christian mathematician, astronomer, physician, and philosopher. Translated many Greek works into Arabic.
- Abū Kāmil. Worked in Egypt, second half of the ninth century. Wrote on algebra, including indeterminate analysis and applications to geometry.
- Al-Nayrīzī. Worked in Baghdad, ninth–tenth centuries. Wrote on astronomy and geometry, including a famous commentary on Euclid’s *Elements*.
- Ikhwān al-Ṣafā’. Tenth century. The “Brethren of Purity” was a group of Ismā’īlī scholars centered at Basra. They incorporated Neopythagorean number theory into their philosophy.
- Al-Uqlīdīsī. Tenth century. Wrote an important book on Hindī numerals.
- Abū’l-Wafā. Lived 940–998, worked in Baghdad. Wrote on astronomy and practical arithmetic and geometry.
- Al-Kūhī. Worked in Baghdad, tenth to eleventh century. Worked in geometry and astronomy.
- Ibn Yūnus. d. 1009, worked in Cairo. Astronomer, astrologer, and poet. Noted for his book of astronomical tables, the *Ḥākimī Zij*.
- Al-Sijzī. Persian, lived ca. 950–ca. 1025. Worked in geometry and astronomy, and made instruments.
- Kūshyār ibn Labbān. Lived ca. 970–ca. 1030. Worked in arithmetic, astronomy, and astrology.
- Al-Karajī. d. 1025. Worked mainly in algebra, number theory, and practical mathematics.
- Ibn Sīnā. 980–1037. Known in Latin as Avicenna, this philosopher and physician also worked in geometry and astronomy.
- Al-Baghdādī. Worked in Nishapur, d. 1028. Mathematician, jurist, and poet.
- Ibn al-Haytham. Early eleventh century. Known as Alhazen in the West, worked in Baghdad and Egypt. Revolutionized the science of optics, and conducted research in geometry and astronomy.
- Al-Jayyānī. Eleventh century, worked in Egypt and Seville. Worked in geometry and astronomy.
- Al-Bīrūnī. 973–1048. Prolific scholar who produced fine work in many areas, including anthropology (his *India*), history, astronomy, chronology, astrology, meteorology, and even pharmacology.
- Al-Khayyām. Lived 1048–1131. Better known as Omar Kayyām in the West. Famous not only for his work in geometry and algebra, but also for his poetry.
- Al-Samaw’al. d. ca. 1175. Jewish mathematician and physician. Worked in arithmetic and algebra, furthering the algebraic theory of al-Karajī. He converted to Islam in his mid-60s.
- Ibn al-Yāsamīn. Worked in Spain and the Maghreb, d. 1204. Wrote popular textbooks on arithmetic and algebra.
- Sharaf al-Dīn al-Ṭūsī. d. 1213. An algebraist who improved on the work of al-Khayyām. Wrote also on astrolabes.

- Naṣīr al-Dīn al- Ṭūsī. 1201–1274. Astronomer, mathematician, and Shi'ite theologian. Founded the Maragha observatory and developed non-Ptolemaic models of planetary motion.
- Kamāl al-Dīn al-Fārisī. Iranian, d. ca. 1320. Worked in number theory, arithmetic, and optics.
- Ibn al-Bannā'. Worked in Marrakech, lived ca. 1260-ca. 1340. Worked in arithmetic, algebra, and astronomy.
- Al-Kāshī. Worked in Samarqand, d. ca. 1430. Famous for his work in astronomy and for his textbook *Key to Arithmetic*.
- Shams al-Dīn al-Khafri. d. 1550. Astronomer who developed multiple models for the motion of Mercury.
- Al-‘Āmilī. 1547–1622. Persian mathematician and theologian whose *Essence of Arithmetic* became the standard textbook in many parts of the Eastern Islamic world down to the nineteenth century.

Key Values

Muḥammad stressed that knowledge (*‘ilm*) is “the driving force in religion and, thereby, in all human life.” (Rosenthal 1975, p. 5). Muslims, and indeed all those mathematicians who participated in the culture, interpreted “knowledge” in a broad sense. Whatever one’s religion, the acquisition of knowledge was viewed as a high virtue.

For the scientist of the ‘Abbāsid court, Sabra expresses the search for knowledge (*‘ilm*) as “to perfect the human soul and prepare it for a state of eternal happiness” (Sabra 1987, p. 23). The later more broadly educated religious scholars found that the study of mathematics, like the study of other disciplines, serves to demonstrate God’s glory.

Conceptualization

Even in its applications mathematics is not intimately connected with many of the following concepts.

Nature/World

This concept is addressed indirectly through the foundations of astronomy.

Reality

The notion of “reality” is not present in most of Islamic mathematics. There was a debate over the reality of the mathematical models of the astronomers.

Knowledge

Two forms of knowledge (*‘ilm*) were distinguished: the native Islamic sciences, which include religion, jurisprudence, and grammar, and the foreign or ancient sciences, which include the mathematical sciences.

Truth

Truth in scientific mathematics was decided by formal proof, following the Greek model.

Perception

Visual perception is described in the optics of Ibn al-Haytham and others. See the entry “Optics and Islam.”

Time

Following Aristotle, most geometers relegated time to the realm of physics and astronomy, not to mathematics proper. But some, in their work on the parallels postulate, defined a line as the path of a moving point.

Rationality/Reason

Mathematicians inherited the Greek conception of rationality, founded on syllogistic logic and formal proof.

Mathematics in Judaism

Ilana Wartenberg

Department of Hebrew & Jewish Studies,
University College London, London, UK

Description

“Mathematics and Judaism” concerns the interface between mathematics and Judaism and examines the use of mathematical principles within Judaism. This domain has not yet established itself as a discipline. Rather, one finds references to this subject matter in analyses of mathematical elements within Jewish literature: the Hebrew Bible, the Mishna, and the Talmud. The analyses of these tracts suggest basic level of mathematics and little interest within Judaism in mathematics per se, with almost no

presence of mathematical abstraction. Ancient Jewish literature adduces concise and practical mathematical information pertinent to daily life and religious matters and helps ensure precise adherence to Jewish law (Hebrew: *Halakha*).

In the Book of Exodus one finds a wide range of numerical data on sizes and weights which are part of the prescription to the Israelites of how to build the various parts of the temple and the elements within. In 1Kings 7:23, the ratio between the circumference of the round vessel “Sea of Solomon” and its diameter (in modern mathematical language: “pi”) is given the rough value of 3.

In the Mishna and Talmud, there are numerous discussions which touch upon an array of mathematical fields: geometry, arithmetic, some elements of game theory, combinatorics, and probability. Geometrical considerations are called for in the legislation on the sowing of fields. According to Leviticus 19:19, two kinds of seeds (Hebrew: *Kil'ayim*, which is the name of the relevant tractate in the Talmud) may not be sown within a certain distance of each other, and thus, different geometrical arrangements for the distribution of seeds are considered.

The square root of 2, an irrational number, that is, a number that cannot be represented as a ratio of two integers, is given a very rough approximation, 1.4 (Babylonian Talmud, tractate Sukah, 8a). Pi is given the value 3, as in the biblical example given above. The rabbis may have been well aware of a more accurate value developed in Greek mathematics, but they may have considered 3 good enough for Talmudic “working purposes.”

An arithmetical theme, which bears calendrical importance, is the rule of divisibility by seven, which helps determine whether a given year is a sabbatical (Hebrew *Shmita*), every seventh year in the cycle, in which any agricultural activity is prohibited (Babylonian Talmud, tractate Avodah Zarah 9b). The Talmud does not provide an explanation for this rule, neither does it present a general discussion of divisibility rules for other numbers. The Talmud solely presents the mathematical rules necessary for the application of Jewish law.

Tractate Kinim (Hebrew for “nests”) in the Babylonian Talmud involves elaborate counting methods regarding possible errors in bird offerings by certain groups of people in the temple service, a very rare and unusual area of Jewish law. One also encounters elements of game theory, that is, the study of strategic decision making in the study of a bankruptcy problem (Aumann and Maschler 1985). The Talmud also makes indirect use of probability and combinatorics rules (Rabinovich 1973).

The mathematical language found within the classical Jewish literature is very basic and lacks the sophistication and abstraction of the Greek mathematical language (Sarfatti 1969).

Relevance to Science and Religion

“Mathematics and Judaism” is extremely relevant to “Science and Religion” since its essence concerns the interaction between the science of mathematics and the Jewish religion and examines the attitudes from within Jewish thought toward the study of mathematics, in particular in the Middle Ages.

During the Middle Ages, the study of sciences in general, and mathematics in particular, seems to have been legitimized and encouraged by Jewish polymaths only inasmuch as it was either propaedeutically or practically useful. In his highly influential *Treatise of the Eight Chapters*, Maimonides (Cordoba 1135 – Fustat(?) 1204) expresses the idea that questions of mathematical nature must not be pursued as ends in themselves. They are commendable only inasmuch as they serve to sharpen the intellect and make one attain the knowledge of the true existence of God. The medieval Hebrew scientific corpus clearly shows great interest and innovation in astronomy but only little original mathematical creation with the exception of Gersonides from Provence (1288–1344) (Freudenthal 1995).

Maimonides uses mathematics to shed light on difficult matters in the Mishna. He addresses the measure of “pi,” stating that its exact value will never be known (even to God) due to its intrinsic nature (or, in modern language, its being an

“irrational number”). In his seminal work, *Mishneh Torah* (Hebrew for “a repetition” of or “second” to the Torah), Maimonides analyzes the role of science and the Greek texts, such as Ptolemy’s *Almagest*, in the context of mathematical astronomy. The eighth part of *Mishneh Torah*, *Sanctification of the New Moon*, is dedicated to the calculation of the Jewish calendar. Maimonides explicitly justifies the study of mathematical astronomy for calendrical purposes, in particular as a tool to calculate the visibility of the lunar crescent (Lévy 2004).

Sources of Authority

The sources of authority for “Mathematics and Judaism” include past and present scholars who wrote on science among Jews in different periods and analyzed the interface between mathematics and Judaism from a scientific, linguistic, social, or philosophical perspective (see references for the (partial) list of scholars).

Conceptualization

Nature/World

Nature/world is not defined explicitly within this domain.

Human Being

Human being is not treated or defined explicitly within this domain, but its mere existence is directly related to human existence and the practice of the Jewish religion.

Life and Death

Life and the origins of death is not treated explicitly within this discipline.

Reality

Reality is not defined explicitly within this domain but several areas in which mathematics is applied within Judaism are closely related to reality. For example, the mathematical principles underlying the Jewish calendar aim to approximate the astronomical reality.

Knowledge

Knowledge is the kernel of “Mathematics and Judaism” since it focuses on the mathematical body of knowledge in service of Judaism.

Truth

Truth is not defined explicitly within this domain but is assumed to be part and parcel of any mathematical framework, and therefore, any mathematical application to Judaism will be assumed to possess intrinsic accuracy and veracity.

Perception

Perception is not defined explicitly within this domain, but it is highly relevant to it, for example, astronomical observations which are embedded into a mathematical model.

Time

Time is a central element within “Mathematics and Judaism” because the practice of many Jewish precepts, such as prayer, requires calculation of a precise time interval.

Consciousness

Consciousness is not of interest within this discipline.

Rationality/Reason

Rationality/reason is not defined explicitly within this domain, but the practice of mathematics is directly linked to the use of logic and reason.

Mystery

Mystery partly belongs to “Mathematics and Judaism,” especially when it comes to the belief that the Hebrew letters possess powers. One often finds calculations of the alphanumerical value of words and analysis of their meaning in the larger context, a practice known in Hebrew as *Gimatria*. For example, the Hebrew word for pregnancy, הריון, has the numerical value 271, which is the number of days a pregnancy lasts, according to Talmudic interpretation (Babylonian Talmud, tractate Niddah 38b).

[Discipline](#); [Language of science](#)

Description

Mathematics and religion is a subdiscipline of the science and religion discipline, which studies the relations between mathematics and the meta-physical language of religions.

We can distinguish three historical stages in the relations between mathematics and religion (Leach 2010).

First Stage: Deductive Rationality

In this first stage, situated in time in the Greece of Pythagoras and Euclid of Alexandria, mathematics used deductive rationality to demonstrate theorems for the first time. Previous to the Greek epoch, several types of algorithms and mathematical relations were known in Egypt, India, China, and Babylon, but the deductive demonstration of mathematical theorems such as the theorem of Pythagoras or the theorems which appear in *Euclid's Elements* had not been developed. As from Greek mathematics, deductive rationality was incorporated as a fundamental characteristic of mathematical language.

At the same time as Greek mathematics was developing its deductive capacity, Aristotle also introduced the deductive method into his metaphysics. In particular, in Book 12 of his *Metaphysics*, Aristotle deductively demonstrates the existence of the *unmoved mover*. The demonstration of Aristotle was again taken up by Saint Thomas Aquinas as one of the ways which demonstrate the existence of God. The unmoved mover is the cause of movement, but, unlike other causes, which, on moving others, they themselves move, the unmoved mover is not moved.

However, on analyzing the logical structure of these metaphysical demonstrations, we see that the difficulty in accepting their demonstrational value, from an analytic-scientific perspective, does not so much lie in the correctness of the argumentation but in the acceptance of the truth of the premises of the argumentation. Once the validity of the premises is accepted, it is easy to check that the argumentation is correct, and

the validity of the conclusion is derived from the validity of the premises. Those who do not admit the argumentations generally do so because they do not admit the validity of the premises.

Second Stage: The Public Language of Science

In the second stage, which commenced in the Europe of the seventeenth century, mathematics acquired the category of the language of science. Mathematicians such as Galileo, Descartes, Newton, and Leibniz used mathematics as the language of physics, expressing their observations through mathematical formulas. Modern physics differs from Aristotelian physics especially due to the mathematical formulation of the laws of nature. In this regard, the mathematical descriptions which Galileo makes of his physical observations and the mathematical descriptions of the laws of physics and astronomy made by Newton in the *Philosophiæ Naturalis Principia Mathematica* are famous.

The use of mathematics as the language of science brought a mechanistic ideal with it. Modern science is distinguished due to defining causes through mathematical formulas. For example, the formula $F = ma$ represents that, for an equal mass, an increase in force is the cause of an increase in acceleration. When expressing causes through mathematical formulas, modern science standardized and mechanized the causes. With the mechanization of the causes, the rationalism of mathematics was incorporated to philosophical and metaphysical language in the seventeenth century. For the rationalists (and in a similar fashion for the empiricists such as Hume), causes can be expressed in a rational-mechanical language. Rationalism may be both believer and nonbeliever.

G. Leibniz is an example of a rationalist believer. He is famous for his idea that nothing occurs in nature without a sufficient reason to explain what has occurred. For Leibniz, everything in the world follows a harmonic plan which preexists in the mind of God and, consequent with this plan, God created the best of all possible

worlds. All the natural and supernatural aspects of this Leibnizian world can be sufficiently understood by rational methods in accordance with the model of mathematics.

While Leibniz attributed the determinism of the world to the mind of God, Pierre-Simon Laplace reached the conclusion that modern science no longer required the hypothesis of God in order to explain the functioning of the world. Laplace's belief that everything has a mathematical explanation suggests the total rejection of metaphysical knowledge. This affirmation is made more explicitly by the British philosopher, David Hume, in his essay of 1748 *An Enquiry Concerning Human Understanding*. This essay is a direct attack on all metaphysical thought. It is also a manifesto in favor of modern empirical science as the sole and true form of knowledge.

We can say that rationalism was a consequence of the scientific use of thought in the eighteenth and nineteenth centuries. As we will see, the mathematics of the twentieth century opened up interesting new perspectives on rationality.

Third Stage: Intrinsically Limited Formal Language

In the third stage, which began at the end of the nineteenth century, mathematical language was formalized. Thanks to the work of mathematicians such as T. G. Frege, G. Cantor, D. Hilbert, K. Gödel, A. Tarski, A. Turing, and A. Church, this formalization made it possible to deduce very important consequences concerning the truth value of mathematical certainties and the intrinsic limitations of mathematical methods.

Thanks to the studies on the foundations of mathematics at the end of the nineteenth century and in the first half of the twentieth century, we have much better knowledge of the cognitive value of mathematics. Together with the attempt by Hilbert to lay the foundations of mathematics, it is also important to study the attempted alternative constructivist foundation of mathematics, found especially in the mathematics of L.E.J. Brouwer.

The constructivism of Brouwer shows that, besides the classical view of Hilbert, there may be other points of view concerning the existence

of the mathematical objects, and it also shows that there is no logical argument which enables a decision to be made regarding whether one point of view is better than the other. Moreover, this pluralism was confirmed, even within the classical view, when K. Gödel made Hilbert's program for the foundation of mathematics fail.

Currently, a large number of mathematicians are not concerned with the foundation of mathematics. The mathematical systems grow, but we do not have the demonstration that each case is consistent, complete, and decidable. Moreover, we do not know for certain whether arithmetic, the central system of mathematics, is consistent. We can say that the trust we have that the building of mathematics is and will continue to be consistent is sufficient.

It is important to draw attention to the point that, although mathematical systems are currently plural, the pluralism of the systems does not deny but rather reinforces the importance of consistency in the interior of each of the mathematical systems. Mathematics is plural but each one of its systems must be consistent. At the present time, we accept consistency perhaps as the final and inevitable point of support of logical thought, and we build a multitude of reasonable systems around this logical nucleus.

The plurality of logical-mathematical systems leads us to also accepting the logical possibility of a plurality of metaphysical options, all of which are consistent. Each of these metaphysical options is forged, in particular, in the personal consciousness, in the context of a community. The metaphysical options are linked to fundamental personal values, shared in community.

The plurality of personal and community options leads us to distinguish between the public language of the sign (proper although not exclusive to mathematics and the empirical sciences) and the personal language of the symbol (proper although not exclusive to metaphysics and theology). The models of the language of the sign are objective and external to personal consciousness. On the contrary, the models of the language of the symbol are inseparably linked to personal and community values. Their meaning is understood and transmitted from personal and community

consciousness. Their translation from one culture to another and the language spoken by a community to another language spoken by another community is not automatic and entails a process of adaptation and integration in another culture.

Self-identification

Science

The subdiscipline of mathematics and religion is a science which studies the relations between mathematics and the language of metaphysics.

Mathematics is a science which, unlike the empirical sciences such as physics or biology, does not study the reality perceived by the senses but through mental intuitions. The semantics of mathematical language is given by the formal models of mathematics which represent mental perceptions.

The study of metaphysical language is also a science distinct from the empirical sciences. Metaphysics uses a type of perception and a language other than the languages of mathematics and the sciences of nature. The meaning of a scientific term refers to an object measurable through the senses. A metaphysical or religious symbol is only understandable within a history, a tradition, and a community which uses this symbol. The meaning of metaphysical symbols depends largely on the community which uses them in order to speak of realities which go beyond the empirical. Metaphysical perception and language seek to achieve absolute knowledge, a framework of reference which can serve us as a permanent view of reality and of the values which flow from this.

When the metaphysical symbols are put together, they give rise to what are called myths or grand narratives common to all the religions and to stories about the origins of the universe or about how the singular human reality appeared. Myth, in this sense, does not mean falsity, but it is rather a traditional story which attempts to meaningfully join together the events and the mysteries of life (Helge and Marie 2010).

Characteristics

Mathematics and religion is distinguished by studying the influence of mathematics and mathematical logic on human rationality in general and on the rationality of religions in particular.

Relevance to Science and Religion

The academic relevance of mathematics and religion in the area of “science and religion” is important for studying the logic proper to scientific propositions and its relation with the logic of religious propositions.

Sources of Authority

The sources of authority for the subdiscipline, mathematics and religion, are those of mathematics and those of religions. In a first approach, mathematics does not have sources of authority as it is thought based on the intuitive perception of certain propositions based on which others are logically deduced. However, mathematics is practiced in schools of logic which are not always compatible with each other. The schools which study the logical foundations of mathematics are sources of authority of mathematics.

Religions, however, are based on personal options which have a strong community component. The communities which practice a religion determine how the sources of authority are established within each religious community.

Ethical Principles

The ethical principles which guide the subdiscipline, mathematics and religion, are respect for and acceptance of the value of the propositions of mathematics and those of the religions. These principles make it possible to reconcile the semantics of mathematical propositions with the meaning of religious propositions. The semantics of the mathematical propositions is intended to be public, equal for all, while the meaning of the religious

propositions is personal and depends on personal values shared in community.

Key Values

The key values of this discipline are rationality, the search for certainty, and the beauty of the thought.

Conceptualization

Nature/World

Mathematics and religion defines relations between two distinct ways of conceptualizing nature/the world, the mental, and formal proper to mathematics and the symbolic-metaphysical proper to religions.

Human Being

It conceptualizes the human being as the subject capable of producing mathematical thought and of expressing himself religiously as a person and as a community.

Life and death

It conceptualize the relations between the mathematical signs which make it possible to describe the evolutionary origin of life and death and the metaphysical symbols by which the religious answers to the question on the meaning of life are expressed.

Reality

It defines concepts which explain the certainty, the applicability, and the formal beauty of mathematics and its relation with the values and meanings which religions attribute to reality.

Knowledge

It defines concepts which relate the formal and public knowledge of mathematics with the knowledge proper to religions which has a personal and community component which characterizes it.

Truth

It defines relations between mathematical truth, conceptualized through formal functions between mathematical objects and religious truth conceptualized through symbols which are interpreted in religious schools and communities (Leach 2008).

Perception

This discipline defines concepts common to the different types of perception of reality, proper to mathematics and religion.

Time

It defines relations between the mathematical concept of time, considered as a formal variable, and the concept of history and evolution in religions.

Consciousness

It defines relations between the consciousness of the consistency of thought proper to mathematics and the consciousness of the values proper to religions.

Rationality/Reason

It defines the relation between the rationality which is expressed in a language of the sign, proper to mathematics, and the rationality expressed in a language of the symbol, proper to religions (Leach 2007).

Mystery

It defines relations between the incomprehensible mystery of mathematics, related to applicability, beauty and the incomprehensible beauty, certainty and mysteries of religions, related to final, global views of reality.

Mathematics in Human Learning

Inés Ma Gómez-Chacón
Mathematics Faculty, Complutense University
of Madrid, Madrid, Spain

Description

Mathematics Education is the teaching and learning of mathematics, as well research on these matters. The researchers in this field seek conceptual and methodological tools and implement approaches which facilitate their study and use. In Europe, research into Mathematics in Human Learning is known as the Didactics of Mathematics (a common denomination, at least, in France and Germany) or Mathematics Education (denomination in United Kingdom).

From the twentieth century, in the developed countries, mathematics began to be implemented as an obligatory nucleus of the syllabus or curriculum. This is when the didactics of mathematics was established as a field of research, and several events contributed to this:

- The creation of the chair of Mathematics Education at the University of Göttingen, in 1893 coordinated by Felix Klein.
- The contributions of Felix Klein, David Eugene Smith, Max Simon, Hans Freudenthal, André Revuz, George Polya, and other mathematicians who encouraged Mathematics Education.
- The foundation of the International Commission on Mathematical Instruction (ICMI) in 1908, which was responsible for promoting scientific work in the area based on the collaboration of mathematicians, psychologists, mathematics teachers, and mathematics professors.
- The training of an international scientific community in the area of Mathematics Education as a result of the First International Congress on Mathematical Education (ICME), held in Lyon in 1969.

From the seventies in the last century, the research area began to be organized. In France, the IREMs (Instituts de Recherche en Didactique des Mathématiques) were created. These were institutes dependent on the Mathematics Departments of the universities and were directed by a mathematician. In Italy and Hungary, Mathematics Education was institutionalized through the university Mathematics Departments, which led to close collaboration between researchers in Mathematics Education and mathematics professors, as in France.

The constitution of Mathematics Education in the Anglo-American area took a different route. In the United Kingdom, the Association of Teachers of Mathematics (ATM) has served as the main support for the articulation of national research projects in Mathematics Education, such as the Low Achievers in Mathematics Project (LAMP) in 1987 or the Shell Centre for Mathematical Education which was set up in Nottingham in 1968. In North America, the researchers in Mathematics Education may be members of Mathematics Departments or professors ascribed to the Education Science faculties (e.g., the National Center for Research in Mathematical Science Education in the USA).

As stated above, if we compare it with other sciences (physics, philosophy, or pure mathematics), Mathematics Education is a very young discipline; however, it does have social relevance as can be judged by the proliferation of journals (Educational Studies in Mathematics, Journal for Research in Mathematics Education, Journal For the Learning of Mathematics, Journal of Mathematics Teacher Education, etc.) doctoral programs, scientific associations and organizations (e.g., the National Council of Teachers of Mathematics (USA), National Centre for Excellence in Teaching Mathematics (England), SEIM (Spain), Homi Bhabha Centre for Science Education (India), etc.), and congresses (ICME, PME, ...).

Self-Identification

Science

Mathematics Education is identified as a science and as a scientific discipline.

If an attempt is made to formulate to what extent this discipline self-identifies among the professionals in the area of Mathematics Education, it will be seen that basic epistemological options constituted by beliefs and conceptions formed from collective and individual experiences related to mathematical knowledge and how the teaching and learning of mathematics comes about and should come about come into play. The underlying mathematical epistemologies in these professionals configure a horizon for the understanding of the identity of a varied discipline (Sierpinska and Kilpatrick 1998) which is at the base of the structuring of their didactic proposals. Thus, we will obtain different characterizations depending on whether we subscribe to objectivist epistemologies with affiliations to Platonism, based on a view of mathematics as a static unified body of knowledge, in which mathematics is only discovered, or a dynamic views of mathematics, heirs of a critical view of science (e.g., constructivist positions, perspective on the resolution of problems), which understands mathematics as a field of human creation in continual expansion, and for

which mathematics is an open science, in construction, and its results are provisional and remain open to revision. In this chapter, dynamic perspective is adopted, in the terms explained above. We consider mathematics as a science with an object of specific study closely linked to historical and sociocultural human development and for which the actions of creating and discovering are the motor forces.

Research into Mathematics Education has two main objectives, one pure (basic science) and the other applied (engineering). The purpose of basic research is to understand the nature of mathematical thought and its teaching and learning. In these studies, work is done on theoretical perspectives in order to understand this nature, and to do so, descriptions of aspects of cognition are developed (e.g., thinking mathematically, what the students understand or fail to understand as regard the concepts of function, limit, etc.) or descriptions of the influence of the emotional, social, and cultural dimensions in mathematical knowledge.

Applied research seeks the applicability of the knowledge achieved in basic research in order to improve instruction in mathematics. Some of these studies are conducted based on proofs of existence (evidence of cases in which the students can learn to resolve problems, induction, the group theory; evidence of the feasibility of diverse types of instruction) and descriptions of the consequences (positive and negative) of different forms of instruction.

Religion

In order to ensure a determined state of opinion, as our starting point we will adopt the definition which the Spanish Royal Academy Dictionary gives of the term religion, “the set of beliefs or dogmas regarding the divinity, feelings of veneration and fear of the divinity, moral norms for individual and social conduct, and ritual practices, principally prayer and sacrifice in order to worship the divinity.” According to this definition, religion is an element of human activity, whose components refer to different environments of individuals and of collectives: comprehension and understanding (beliefs), affective

existential experience (feelings, the supernatural dimension), and conduct (ethics and morality of behavior).

If we apply this definition literally to the concept of Mathematics Education, we can affirm that this knowledge does not comply with the parameters established for a religion and it should be added that the dialogue with religion does not become a necessity for mathematics nor for Mathematics Education. Nevertheless, as was noted in section “[Religion](#),” Mathematics Education as a scientific discipline is structured based on a determined epistemological foundation; therefore, it participates in a view and ways of accessing knowledge marked by systems of beliefs of the collectives which work on these. Beliefs do not only refer to the human construction but also, very especially, to mathematical production and the view of the world. Therefore, we could state that religion and Mathematics Education share similar grounds (mathematical metaphysics, philosophical presuppositions of what knowledge is), whose foundations are supported by systems of beliefs and ways of conduct founded on ethical attitudes. This common substratum makes it advisable not to reduce the environment of mathematics and of Mathematics Education to web of systems and results which, however rich and complex they may be, seem to us to be insufficient.

It may be pertinent to point out here that, throughout the history of mathematics, we find mathematicians and collectives of mathematicians who have been led to perceive mathematics as a model and mirror of what human conduct must be and as the object inspiring astonishment and mystery (so linked to the religious phenomenon) by the “certainty” of mathematical knowledge, the order and harmony of the universe discovered through the contemplation of the structures and rhythms of nature. In the case of the Pythagorean school, the revelation of the harmony of the universe expressed in the harmony of the numbers provided a path to union with the divine. It could be said that, on contemplating the independent force and autonomy of the relationships which are created or discovered in mathematics, mathematics can reasonably suspect the

presence of something superior to it, which precedes it in intelligence. This conviction crosses the history of mathematics, and we can trace it to Hermite (and Gödel), in its affirmation of the divine origin of the world of mathematical ideas and on the construction of a rational religion based on its logical-philosophical thought or in the formal proofs of the existence of God (Anselm, Leibniz, Gödel).

Characteristics

Mathematics Education is not a particular case in general education. It is important to point out that, although the object of Mathematics Education is mathematics, the epistemological status of this knowledge is different from the mathematics investigated by mathematicians; the nature of the evidence and of the argumentation is different in both disciplines. Mathematics Education must necessarily refer to the person in his global nature, a person still to be conformed, integrated into a specific society, and modeled by the culture in evolution of the society he belongs to; Mathematics Education must unfailingly have the human and material resources required at a specific time and must be aimed at the finalities assigned to education by a determined society, through its political authorities, finalities which can be extraordinarily varied.

Mathematics is characterized by the fact that its studies mental creations, it does not work with objects or physical phenomena, and by the form in which its declarations are justified. Mathematics has its own characteristics such as abstraction, induction, hierarchy, globalization, rigor, which entails an epistemology of its knowledge. Mathematics is a discipline which requires a certain effort for its assimilation and the use of cognitive strategies of a superior order. Mathematics Education is characterized by the application of forms, methods, and strategies which inform the conscious action of the mathematical work in the person learning. To achieve this, it is necessary to have an interdisciplinary approach, which takes into consideration a variety of theoretical frameworks: epistemology, psychology, the sociology of mathematical knowledge.

As the necessary interdisciplinary condition is not sufficient, Brousseau and Artigue in the ICMI Study Conference (p. e., Artigue 1998) pointed out that the questions of meaning and genesis of the mathematical notions are a meeting point for researchers into Mathematics Education and researchers into mathematics. Without this specific contribution, Mathematics Education would run the risk of becoming didactics of a general type.

Relevance to Science and Religion

In relation to the subject *Science and Religion*, we tend toward an approach which makes it possible to have elements of differentiation, dialogue, and integration between both disciplines and we consider that a pertinent relationship between *Science and Religion* can be established based on *complementariness*. In the first place, the differentiation is sustained because *Mathematics Education* and *Religion* conserve their legitimate identities and autonomy in the domains recognized for each of them by the respective scientific communities. Each of these disciplines is autonomous when defining their universes and each is free to advance along its own path.

It should be asked whether, despite being disciplines with such different identities and languages, a space, a common territory can be established in which both can dialogue and interact. The response would be affirmative. On the one hand, science (Mathematics Education) is an instrument which forms the subject as regard his perception of the world and the nature of the person who it humanizes and perfects (the human mind, system of values, etc.); on the other hand, religion needs consistent subjects, who provide sense to human action considered globally (the holistic dimension).

From this point of view, it could be stated that *Mathematics Education* incorporates elements which are related to the metaphysical dimension. In the mathematization process, the human mind finds indications, clues which make him suspect the existence of something in the universe beyond him; this opens up the question on reality, on

existence, on being, on the how and the when, on where from and where to; all these questions involve interrogations on axiology and meaning. In this opening of the mind to intellectual mathematical knowledge, being is present as a horizon and a possibility in its infiniteness and the perception of an infinite horizon in knowledge, which stimulates the search for its foundations. Thus, the mathematical mind is opened up to the possibility of moving with no difficulty from specific thought on a specific problem to what is mysterious and transcendent, entering a dynamic search for what the mysterious and the inexpressible/ineffable represents in the mind.

The opening up of our minds is not only the opening up and the dynamism of intelligence but that the person intervene holistically (the whole person; with his willingness; with his capacity for desire, love, freedom, structure of values, etc.).

The teaching and learning of mathematics which is rooted in humanist approaches, undoubtedly, contributes to the fact that the person who learns gradually discovers human values with all their nuances (including absolute values). This discovery acquires more significant qualities to the extent in which it is supported by person to person and person to reality interaction (including mathematical reality). Educational action from mathematics can help to identify and discover dimensions of value within the framework of these interactions. The learners not only discover values but also live them; they transform these into conduct, thoughts, actions, and all kinds of experiences.

Among pure mathematics and technological applications, there is a wide spectrum of mathematical activities which have the search for coherence, clarity, certainty, and effectiveness in the development of knowledge in common. During the learning of mathematics, coherence and the needs of mathematical work do not enclose the learner in a mechanical and automatic control of reality but bring him close to the unexplored and the unknown, to creativity and intuition, to the passion to discover new worlds. It also opens them up to the nonformal world of metaphysics and theology.

If this process is to be feasible, a determined type of mathematical epistemology must govern the learning. An epistemological approach of an ahistorical, amoral nature, isolated from the scientific disciplines, deprived of cultural emotions and values, only formed by a body of facts and truths, a conception which has dominated many of our syllabuses (curriculum) for a long time, would not be feasible. It would be advisable to propose mathematics and education of a humanist type. In the humanist approach, the perspective of the professor, of the educator as a mediator in the learning process, is vital. The professor and his conceptions of mathematics are irreplaceable as regard the revelation and the development of values which can make the learner ask questions on the nature of certainty, truth, existence, limits.

Finally, it should be mentioned that, in some countries, in the *Science Religion* dialogue, materials have been published on the learning of mathematics at secondary school level, taking the social responsibilities which this science assumes in each context (the axiological structure of the science) as the reference and production framework. We refer to the Charis materials, drafted by members of the Association of Christian Teachers (Scott et al. 1996). These decide for the option to establish connections between spirituality, charity, and social justice, connections which lead the subject to a search for an explanation of the world in terms of religion, philosophy, science, and mathematics.

Sources of Authority

As in other disciplines, one of the sources of authority of Mathematics Education lies in the methods which make the validation and feasibility of research possible. The results of the research in education are not “proved” in the sense that mathematics is proved. Frequently, experimental methods or direct statistics (of the type used in the physical sciences) are inadequate or insufficient due to the complexity of deciding what is meant by educational conditions being “replicated.” Thus, in Mathematics Education, it

is necessary to have recourse to a wide variety of methods of a heuristic or interpretational nature. For example, a look at the study of research into the teaching of calculus in university Mathematics Education in recent decades shows this variety (Schoenfeld 2000). Along the same lines, we find reports of detailed interviews with students, comparisons of calculus courses under the reform with traditional courses and a broad study on the development of the comprehension of calculus in students through the use of learning technologies. These studies, which use anthropological and sociological techniques of a qualitative nature, are increasingly more common in Mathematics Education.

It is also usual that the use of these types of techniques gives rise to questions on their validity and feasibility. In order to neutralize the suspicion, Mathematics Education has a number of criteria for evaluating models, theories, and, in general terms, any empirical or theoretical work; these criteria are the following: descriptive power, explanatory power, scope, predictive power, rigor and specificity, the possibility of refutation, replicability, availability of multiple sources of evidence (“triangulation”). The findings achieved are rarely definitive. With these types of techniques, the results always become provisional and, frequently, they are tentative, like human existence. The evidence, in these cases, does not adopt the form of mathematical proof but is accumulative, progressing toward conclusions which can be considered to be tendencies or reasonable models with explanatory power for the reality they study.

Ethical Principles

Mathematics as a science is one of the fundamental axes of culture and contracts a singular responsibility with culture for its proper development; a development which could be said to be *at human scale*. Mathematics, as a formal science, cannot assume the pretension of neutrality; together with other disciplines, it is unfailingly linked to the improvement of the standard of living of the citizens. In this same regard, numerous

aspects of mathematical work and its teaching strongly involve our sense of responsibility as members of a global society. This orientation is included in declarations of institutions and the contributions of mathematicians (American Mathematical Society Ethical Guidelines (<http://www.ams.org/secretary/ethics.html>); interview with Reuben Hersh, What Kind Of Thing Is A Number? A Talk With Reuben Hersh [2.10.97] (http://www.edge.org/3rd_culture/hersh/hersh_p1.html; Moslehian 2005; Guzmán 2000). Among the ethical principles we can point out the submittal to reality; the joyful acceptance of truth and beauty; professional integrity; the deep sense of humility in the search for knowledge; the sense of freedom, of community, and cooperation with others; the respect for mathematical capacity wherever it may be, regardless of race, gender, ethnicity, age, religious or political orientation, etc.

Key Values

In the last two decades, much effort has been made to identify the set of values associated to mathematical knowledge and its teaching (Brown 1996). As a suggestion, and with the provisional nature of all contextualized knowledge, we propose the categorization of Bishop (1988) which, based on the four components of culture of White (1959): sentimental, ideological, sociological, and technological, organizes six sets of values grouped in three binomials: *rationalism– empiricism*, *control–progress*, and *opening–mystery*.

Rationalism is related to the discussions, reasoning, logical analysis, and explanations. This value is revealed by the teacher when he evaluates the development of the capacities of the students for argumentation, logical reasoning, and mathematical proofs. *Empiricism* is related to the processes of conversion into objects, specification, and the application of ideas in mathematics. The teacher will show this in his classes when he estimates the development of the practical capacities of the students for the use of the mathematical ideas and symbolism in modeling through diagrams and in the collection of experimental data.

Control relates to the potentiality inherent to mathematical knowledge for the use of established rules, procedures, and criteria; of facts; and of predictions. This value is inculcated by the teacher when he appreciates the capacities of the students when presenting routines and algorithms, when working with mathematical precision, and when exploring mathematical ideas which predict events. *Progress* is related to the development of mathematical ideas, of individual freedom and creativity; the teacher can foster this in teaching through the stimulation of creative explanations.

The *opening up* refers to the democratization of knowledge through proofs and through individual explanations. The teacher can foster this value when he stimulates the development of the capacities of the students to structure their own ideas in proofs, verifications, discussions, and in the freedom to express different points of view.

Finally, *the mystery and the search for truth*, this value is related to the fascination for scientific mathematical ideas and with submittal to the truth and to reality, so rooted in the scientific. This value, undoubtedly, constitutes one of the important features which we should appreciate and encourage in the teaching of mathematics. The teacher can stimulate the imagination of the students in discussions on the nature of the object knowledge and the meaning of the scientific ideas.

Therefore, besides being a determined class of symbolic technology (rules, concepts, algorithms, etc.), mathematics is the carrier and, at the same time, the product of determined values. If we only wish to understand mathematics as a specific symbolic technology, we will only understand a small part of these, perhaps the least relevant for education and for our future as human beings.

Conceptualization

Some of the concepts which are defined below are not the objects of study, not of definition in Mathematics Education. In the event that this is done, it should be pointed out that it is not

possible to establish a univocal definition because this will depend on the theoretical framework of reference which is adopted. Therefore, we will define these, taking this into account.

Nature/Word

Mathematics is an exploration of certain omnipresent and more or less complex structures which appear in nature, in the world; which admit this rational approach, which can be manipulated through symbols; which provide us with a certain domination of the reality they refer to; and which we call mathematization. For example, in the *mathematics for a realist education* focus, mathematics begins and remains in reality. Mathematical activity commences in processes of mathematization of the real and is expressed in rules, in *structures*, which in turn become the base material for superior abstraction, generating a hierarchy which is distant from the original common sense until it is converted into the reality most distant from this.

Human Being

In Mathematics Education, focuses such as the resolution of problems and the constructivist perspective place special stress on the human being as the person who creates and constructs mathematics. The human being is not a concluded being but is a being who becomes within the evolutionary framework.

The transmission of mathematical knowledge is carried out by paying attention to specific persons under a holistic perspective of the integration of the cognitive, affective, and social dimensions of the subject.

Life and Death

These are not the objects of definition by the discipline.

Reality

In relation to this concept, it seems to us to be significant to point out one of the facets which is most worked on in Mathematics Education, the objective view of reality. Mathematics fosters a view of reality which is more objective than subjective. The ideas are essentially ideas on objects.

Mathematics deals with abstractions, and Mathematics Education puts substantial efforts into developing what is usually called *abstract thought*. The power to *convert these abstractions into objects* is what makes it possible to handle these with such precision. In addition, the network of logical connections developed with mathematical ideas through proofs, extensions, examples, counter examples, generalizations, and abstractions helps to give them objective meaning, and consequently, it makes it possible to *address these as if they were objects*. The language of if; we suppose and the conditional tense of the verb also force an imagined reality at conscious level and, thus, it permits this to be manipulated *as if it were* an objective reality. Therefore, when encouraging the students to develop their capacity of abstraction, we encourage the ways to specify and “convert abstract ideas into objects” through a wide range of symbols.

Knowledge

Mathematics, like any other type of knowledge is created, applied, and taught within the framework of institutions whose use and values have significant repercussions on the way to focus learning and on the approaches of Mathematics Education. For example, in the constructivist positions on Mathematics Education, knowledge refers to the ordering and organization of our experiences and not to the understanding of an objective ontological reality. In order to provide grounds for their proposals, the constructivisms found several psychological referents, Piaget and Vygotsky, whose theories of knowledge are wider than the epistemology of mathematical knowledge. There are philosophical presuppositions on what knowledge is, and there is an option to decline any type of correspondence with the world in order to define truth and objectivity. The proposals of radical and social constructivism are important examples of these types of conceptions which give rise to beliefs which influence the teaching and learning of mathematics.

Truth

From its beginnings, mathematical knowledge has been considered to be sure, absolute, and

eternal knowledge. However, in the twentieth century, epistemological approaches appeared and, currently, these have an important influence on the teaching of mathematics and present mathematical work as fallible. The mathematical truths, propositions, and ideas in general are open to the examination of any properly trained person. According to this focus, the education process must be centered on a heuristic focus which is set against the deductivist focus of the formalist school (e.g., Lakatos 1976). The deductivist focus starts from the acceptance of primary truths and definitions, without explaining how these arose, and from these, the theorems and proofs are presented. On the contrary, the heuristic focus shows the counter examples; it does not separate the definitions from the proofs which have generated them; it places emphasis on problematic situations and stresses the *logic* of the discovery which has given rise to new concepts. The perspective opened up by the approach of heuristics endeavors to show the side of mathematics hidden below the Euclidean rigor and presents it in its process of genesis toward a new level (Polya 1945). The creative phase in mathematics is not governed by logical analyses, but by inquiry which must opt for new views, to relate concepts or properties and create new ones. The consequences of this approach for Mathematics Education are substantial, and, in recent decades, their effects have begun to be seen. Among its more disseminated tendencies is the accent on the transmission of processes of mathematical thought and, in particular, on the mental processes for the resolution of problems.

Perception

Perception and action are bases of mathematical thought. We understand *perception* to be the exercise of a first level of awareness faced with contact with reality. The development of perception implies extending the capacity to be aware, to note, to highlight elements and aspects which configure what surrounds us until it is configuring the subject which it constructs more and more actively. In Mathematics Education, attention is paid to the blocks which more specifically affect our cognitive functioning, the perceptive blocks. These are

obstacles which prevent anyone from solving a problem from clearly perceiving the problem in itself or the information required to solve it.

Time

In some subdisciplines such as the didactic of mathematical analysis, the changes and transformations in space and time are analyzed.

Awareness

Education basically consists of educating the attention, producing changes in the locus, in the focus, and in the structure of attention, and these changes can be increased through others, working in the awareness itself. The act of awareness is an internal individual activity which a student carries out but which is more easily achieved if the educational activity fosters it. Several strategies can favor this. For example, one strategy is that the teacher work with the awareness that the students have of mathematics instead of expressing his own awareness of mathematics. Another strategy is the development of an internal mathematical monitor which presents us with questions such as, "Why am I doing this particular operation?" "Is it supposedly more complicated?" and "Am I doing this wrong?" Developing a monitor which corrects errors is an important part of the metacognition involved in becoming an expert in mathematics.

Rationality/Reason

In this discipline, the mission of the human mind consists of rationally interpreting realities, facts, which are presented as given, as previous, to the best of its ability.

Mystery

The work of *mathematics* is necessarily an open activity, *inexhaustible*, in the sense that it can never be considered to be concluded; the mystery is linked to the fascination for new mathematical ideas and the perception of the infinite.

Relevant Themes

Finally, we should point out something which we have shown in this document, which is that in

the development of the discipline of Mathematics Education, there are different focuses. The conceptions of the knowledge of the world included in each of these focuses have repercussions in the education of the students and can become indirect ways of familiarizing them with different ways to see the world and to conceive objectivity and truth, and, as a consequence, to place the bases for their conception of moral responsibility.

Mathematics in Latin America, History

Clara H. Sánchez and Víctor Albis

Departamento de Matemáticas, Universidad Nacional de Colombia, Bogotá, Colombia

The history of mathematics in Latin American countries is a very recent area of research D'Ambrosio & Selin (2001). Most of this research has been carried out since the 1960s and continues today with exceptional vigor. In general, it has been done by mathematicians who have a particular and deep interest in the history of the development of mathematics in their own countries. This activity has led to the creation of specialized journals in the region such as *Revista Latinoamericana de Historia de las Ciencias y las Técnicas*, *Mathesis*, and the *Revista Brasileira da História da Matemática*. Research results have been published in these journals as well as in other journals such as *Historia Mathematica*, *Llull*, and journals of national academies or mathematical societies. Some national and international associations have also appeared to organize and cement these activities. However, it is worthwhile to note that a technical report on the contribution of Latin America to world mathematics was made for UNESCO by the Science Corporation Office for Latin America in 1950 (Luis et al. 1951). The following historical periods have tentatively been proposed: pre-Hispanic D'Ambrosio (2006), the colony, the nineteenth-century-independent countries, first decades of the twentieth century, and the rest of the twentieth century.

First period: Pre-Hispanic period. The pre-Hispanic period goes up to the first decades following the discovery of the American continent. In this period, the counting practices and the underlying plane symmetries in the decoration of monuments, gold work, pottery, and textiles are studied as part of the mathematics developed by the pre-Hispanic American cultures.

Second period: Colony. The colonial period comprises the sixteenth, seventeenth, and eighteenth centuries. The teaching and use of mathematics (including astronomy, physics, and nautical sciences) at universities established at the different Viceroyalties and elsewhere are taking into account.

Third period: The nineteenth-century independent countries: This period goes from the 1810s up to the 1890 s, when the intellectual and political elite leaders of these new countries became aware of the importance of science and techniques in the economic and scientific development of these nations, since they would provide the means to construct a badly needed infrastructure (represented in roads, railroads, ports, and factories) and also the formation of able military officers to defend their new acquired sovereignty. Research and analysis in this period attempts to establish mathematics in military, university, and high school institutions, as a necessary premise for the social and economic development of Latin American countries.

Fourth period: First three decades of the twentieth century: The first decades of the twentieth century in math are historically void in most of the Latin American countries, except for the interest in the formation of teachers of mathematics for secondary and engineering schools. This period is characterized by a deep stagnation in the learning of advanced mathematics with the exception of Argentina (Ángel, 1995; da Silva, 1992; Sánchez Fernández Carlos & Valdés Castro Concepción, 2003).

Fifth period: The remaining decades of the twentieth century: This period correspond to the consolidation and development of modern mathematics in the region.

The history of mathematics in Latin America is part of the history of mathematics, the history of science, and the history of Latin America. In particular, it is interested both in the specific developments in mathematics and also in the social aspects about which the work was done.

As part of the history of mathematics, the history of mathematics in Latin America does not identify itself as a religion. Nonetheless, the works of Seidenberg (1961) on the ritual origin of

counting and geometry in primitive societies demonstrate deep relationships between mathematics and rituals. This awakens interest in these cultures' conception of the world, especially its creation. Nonetheless, it is noteworthy to remark that these relationships are actually used by some educators to teach mathematics to ethnic groups. This activity is called now ethnomathematics and began as such in Brazil with the works of Ubiratan D'Ambrosio (D'Ambrosio 2006).

The main primary sources for doing history of mathematics in Latin America are the archives related to national histories, in particular, the National Archives and those of Secretaries of War and Education, universities, and other academic institutions. The secondary sources are books and papers published by very respected and reliable mathematicians interested in the history of mathematics in their respective countries during the second half of the twentieth century. Some recognized journals are *Quipu*, *Llull*, *Mathesis*, *Revista Brasileira de História da Matemática*, and journals from the various Academies of Science. There are also some papers on the Web with relevant information on the history of mathematics in specific countries of Latin America.

The history of mathematics in Latin America, as part of the more general history of science and culture, must provide accurate knowledge about the development of mathematics and its impact in the region and the rest of the world. Mathematics serves to model the natural, economic, and social world. Its history in the region supplies information as how these aspects have been apprehended and used in Latin America. This, in turn, helps in designing appropriate strategies to improve the quality of education, especially in mathematics and in science, in order to cope with regional social and economic underdevelopment. Thus, the history of mathematical education is closely related to the history of mathematics.

Related Terms

[Logic](#); [Metaphysics](#)

After the boost given by the Greeks to mathematics, there was a long period in which creative

mathematical activity declined in Europe. During the Middle Ages (Folkerts 2003, 2006), especially outstanding were the research and discoveries regarding algebra carried out in the cultural environment of Islam.

Interactions Between Logic and Metaphysics in the Medieval Period

The Greeks introduced logical arguments in mathematics and metaphysics. Medieval Christian theologians combined Greek rationality with Christian metaphysical statements (Plantinga 1967). Among the medieval arguments about the existence of God, the ► [ontological argument](#) (Hintikka 1969) shows with particular clarity the problematic relation between mathematical logic and metaphysics.

The Ontological Argument

The ontological argument is a type of reasoning on the existence of God based on *metaphysical propositions* about the existence of a necessary being and *logical reasoning* (Leach 2010). The ontological argument stands out by its uniqueness among the argumentations which seek to show the existence of God a reasonable choice.

It is noticeable that some philosophers accept the ontological argument while others, even as accepting the existence of God reasonable, do not accept the ontological argument. *Thomas of Aquinas* (1225–1274) and *Kant* (1724–1804) reject the ontological argument, while other philosophers such as *Avicenna* (980–1037), *Anselm of Canterbury* (1033–1109), *Descartes* (1596–1650), *Leibniz* (1646–1716) and *Spinoza* (1632–1677), *Gödel* (1906–1978), etc., accept it.

Ontological Argument, Logic and Mathematics

There are several versions of the ontological argument, but in order to formalize them adequately, we need to use not only logical *formal signs* but also *metaphysical symbols* in all of them.

The Formal, the Real, and the Metaphysical in the Ontological Argument

The main difficulty posed by thinkers such as Thomas of Aquinas and Immanuel Kant as regards the ontological argument is that, from the mere analysis of the concept of existence, it is not possible to deduce the real existence of anything. Their difficulty is based on the fact that, in the ontological argument, a leap is made from the logical to the real, from the mental to what really exists.

The distinction between the propositions concerning formal existence in mathematics and real existence in the empirical sciences and in metaphysics helps us to reveal the confusion of opinions on the ontological argument.

Three Types of Propositions Concerning Existence

We can distinguish three types of propositions concerning existence: propositions of mathematics on formal existence, for example, there is a solution to the equation $x^2 = 4$; propositions of empirical sciences regarding real existence, for example, there are eight objects in the solar system with the category of planets; and metaphysical propositions on infinite and unconditioned existence, for example, God necessarily exists because God's essence is to exist (Baruch Spinoza, Part I of his *Ethics*).

Historical Formulations of the Ontological Argument

One of the first historical formulations usually cited regarding the ontological argument is that of the Muslim scientist and philosopher *Avicenna* (980–1037). In *The Book of Healing*, Avicenna distinguishes between the essence (*mahiat*) and the existence (*wujud*) of beings and postulates a being whose existence is necessary (*Wajib al-Wujud*).

After Avicenna, there have been other thinkers who have sought to show the rationality of the existence of God based on conceptual propositions and postulates concerning existence with no limitations and on logical reasoning. Outstanding among these was *Saint Anselm of Canterbury* (1033–1109) who based his argumentation on

the idea of God as the greatest being we can think of "... we believe that thou art a being than which nothing greater can be conceived ... And assuredly, that than which nothing greater can be conceived cannot exist in the understanding alone: then it can be conceived to exist in reality, which is greater." (A current version of the Works of Saint Anselm translated into English can be found at <http://www.sacred-texts.com/chr/ans/>.)

René Descartes (1596–1650), Gottfried Leibniz (1646–1716) and Baruch Spinoza (1632–1677) have different formulations of the ontological and of Anselm. Kurt Gödel (1906–1978) formalized the argument of Anselm in modal logic (Fitting 2002). (Modal logic is differentiated from classical logic by the fact that it admits propositions affected by modalities such as "possibly" or "necessarily.")

Although they are different as regards their formulation, all the ontological arguments have in common the fact that they are supported by propositions of metaphysical type concerning the concept of a being without limits (or, using the words of Anselm, refer to a being such that we cannot think of any greater being), and based on these propositions, they argue the reasonableness of the existence of God.

A simplified formalization of the ontological argument OA in predicate logic is as follows:

-
- (1) We cannot think of a being whose existence is more necessary than that of God
 - (2) If God does not exist necessarily in reality, then we can think of a being whose existence is more necessary than that of God
-
- ∴ Therefore God exists necessarily
-

Formalization of OA

We define:

-
- $M(x,y)$: We can think that the existence of x is more necessary than the existence of y
-
- $EN(x)$: x necessarily exists in reality
-
- d : God
-

Then OA:

-
- (1) $\neg \exists x M(x,d)$
-

(continued)

(2)	$\neg \text{EN}(d) \rightarrow \exists x \text{M}(x,d)$
$\therefore$	$\text{EN}(d)$

where we can read the premises (1) and (2) and the conclusion therefore as follows:

(1) $\neg \exists x \text{M}(x,d)$	There does not exist an element of our domain of discourse x such that we can think that the existence of x is more necessary than that of God
(2) $\neg \text{EN}(d) \rightarrow \exists x \text{M}(x,d)$	If God does not exist necessarily, then there is an element x whose existence we can think is more necessary than that of God
$\therefore \text{EN}(d)$	God exists necessarily

In the formalization of OA, we have used two different signs, the logical sign $\exists$ and the predicate EN, in order to denote the existence of the same element x . The use of the logical sign $\exists$ in formula (2) indicates the existence of an arbitrary element x of our domain of the discourse to which we attribute the predicate $\text{M}(x, d)$. The use of the predicate EN in the subformula $\neg \text{EN}(d)$ indicates the necessary nonexistence of d , whereas the formula $\text{EN}(d)$, the necessary existence of d .

It is easy to verify that, by applying the rules of deduction of classical logic to the formal propositions (1) and (2), the conclusion $\therefore$ follows.

We can construct a formally correct ontological argument and conclude that God exists, in the case that the two premises (1) and (2) are true. However, the problem stated by Thomas of Aquinas and by Kant regarding confusing formal existence in thought with real existence has not been solved because in premise (2) we are mixing the logical sign $\exists$ which refers to formal existence with the predicate EN which refers to necessary real existence. That is to say, we are mixing the real world with the mental world without adequately distinguishing these.

Empirical and Metaphysical Propositions

We know that, in the physical and empirical sciences, the propositions which include predicates which refer to real existence need to be confirmed by sense observations of reality.

For example, we know that a proposition of the geometry of Minkowski becomes a proposition of the theory of relativity if this is confirmed by observations of reality. Likewise, the propositions of a metaphysical type, which refer to unconditioned existence, also need to be confirmed by visions of a metaphysical type concerning necessary existence and, therefore, unconditioned existence.

For Anselm, Descartes, Avicenna, and many others, who have considered the ontological argument valid with several variants, the proposition $\neg \text{EN}(d) \rightarrow \exists x \text{M}(x, d)$ expresses a metaphysical vision of the reality. The metaphysical vision is not felt like the empirical experience and is not thought out like the mathematical and logical intuition; it has its own way of being thought and felt.

Saint Anselm and other defenders of the ontological argument reasoned correctly from a formal point of view. Their conclusion is valid in the case that the following metaphysical proposition is valid: “If God does not necessarily exist, then there is an object of our metaphysical intuition whose existence we can think as being more necessary than the existence of God.” But, the validity of this metaphysical proposition is not accepted by all thinkers.

Mathematics, Early

Javier Leach

Facultad de Informática, Departamento de
Sistemas Informáticos y Programación,
Complutense University of Madrid, Madrid,
Spain

In the prehistory, before there were writing systems, we have archaeological evidence of representations of *geometrical figures* and of instruments used to make *numerical calculations* (Katz 1998). Before Greek civilization (D'Ambrosio and Selin 2001), there was an intuitive knowledge of mathematical relations and theorems which was first proved by the Greeks (Boyer 1991).

Infinite in Mathematics and in Religion

Apart from the mythical use of finite numbers in Egypt, Babylon, India, and other pre-Greek cultures (Katz 2007), the infinite is one of the first concepts relating mathematics and religion (Plotker 2009). The Yajur Veda, one of the four canonical texts of Hinduism, uses the concept *purna* and states that if we subtract *purna* from *purna* what remains is again *purna*.

The use of the concept *purna* in the Yajur Veda can be interpreted both religiously and mathematically. The word “infinite” is used in three different contexts, as a mathematical sign, as a sign representing a quality of the empirical reality, and as a metaphysical symbol. This can lead to confusion.

The Mathematical Infinite

As a *mathematical sign*, the infinite can have two distinct meanings: *potential infinite* and *actual infinite*. The potential infinite is a succession of objects which can be as big as we wish as it does not end. Otherwise, we can consider the actual infinite as a whole. For example, we can consider the natural numbers as a succession of numbers $N = 1, 2, 3, \dots$ that does not end or we can

consider all the numbers of N as a whole $N = \{1, 2, 3, \dots\}$ and call this whole actual infinite (Boyer 1991).

Cantor proved that the consideration of N as a set actually infinite leads us to consider other infinities which are “greater” than N , called *transfinite numbers*. The difficulty to understand transfinite numbers led some constructivist mathematicians to deny their existence (Morris 1990).

The Empirical Infinite

The infiniteness of time and space is a physical concept which refers to the real world and which is frequently confused with mathematical infiniteness. Different physical options concerning the infinitude of time and space in physical reality are based on different physical paradigms. It is impossible to take infinite small or infinite large measurements (Gardiner 2002).

The Metaphysical and Religious Infinite

Finally, the *infinite* is used as a *metaphysical symbol* representing the *transcendent*, *ultimate* and *definitive* existence, whereas the metaphysical symbol *finite* means the *nondefinitive* existence.

Frequently, religions state that God is infinite because we cannot define or delimit His names through human concepts. The religious and metaphysical understandings of infinite are symbolic and include a personal option accepting or rejecting the existence of an infinite, ultimate, and definitive reality.

Arithmetic

One feature that characterizes this epoch of mathematics is the *formalization of mathematical language*. The formalization had two important consequences, which influenced the global nature of mathematical and scientific knowledge.

The first consequence was the possibility to *study the mathematical language with mathematical methods* (Benacerraf and Putnam 1983). Just as mathematics proves theorems about numbers, straight lines, planes, geometrical figures, and other mathematical objects, in this last epoch, mathematics has been able to prove theorems about the very language of mathematics and its meaning.

The second consequence of the formalization of mathematical language was the ► *automation of mathematical proofs*. The automation of mathematics has brought the human mind next to the computer. Once formalized, the mathematical proofs can be translated into a programming language and be executed by computers.

Truth and Certainty in Formal Math

The formalization of mathematics brought about a new type of mathematical certainty based on formal methods (Leach 2010). The traditional

mathematical certainties were based on intuitions and proofs whose consistency was proved to be at times doubtful. The new formal methods made it possible to prevent paradoxes and have provided the capacity to prove mathematical consistency on some occasions.

The certain knowledge offered by mathematics in this new stage responds to an old metaphysical aspiration: the certain, consistent knowledge of truth. However, in order to achieve this certainty, it was necessary to pay a high price: the reduction of truth to the environment of the formal. The new formal certainty is the basis of interesting, complex relationships which were established between science and metaphysics throughout the twentieth century and at the beginning of the twenty-first century (Tymozco 1998).

We can divide this historic epoch in three phases:

1. First phase. The origin of formal mathematics

The appearance of non-Euclidean geometries showed that geometry did not depend on the traditional intuitions which supported it. *Nikolai Lobachevsky (1792–1856)* developed a new non-Euclidean geometry that relativized the value of the traditional geometric intuition and stressed the absence of contradiction in the deductions.

George Boole (1815–1864) published in 1854 *An Investigation into the Laws of Thought* in which he described with algebraic methods what today we call the logic of propositions. *Gottlob Frege (1848–1925)* completed the formalization of the mathematical language which Boole had begun. In 1879, Frege published *Begriffsschrift*, “Concept Notation,” with the subtitle, “a language of formulas for pure thought in the likeness of arithmetic.” *Georg Cantor (1845–1918)* defined a set as “a collection into a whole of definite and separate objects of our intuition or our thought.” The idea of collection helped Cantor to express what mathematical objects are in a uniform way: collections of elements. As a result of set theory, mathematics acquired standard semantics.

The formal results of Boole, Frege, Cantor, and others had prepared the terrain so that

David Hilbert (1862–1943) could put forward the study of mathematics with mathematical methods. This study is called metamathematics. The metamathematical program intends to prove that the mathematical theories are *consistent*, *complete*, and *semantically decidable* by metamathematical finite resources. A theory is consistent when we cannot deduce a contradiction within it. A theory is complete if any true formula in the system can be formally proved from certain axioms. And a theory is semantically decidable if we have a formal procedure for deciding whether a given formula is true in a given model or not.

2. Second phase. The incompleteness of arithmetic

Kurt Gödel (1906–1978) (Casti and DePauli 2001) proved that first-order logic was a complete system. However, later on, by using metamathematical methods, Gödel proved in 1931 that the formal system of arithmetic is incomplete (Smith 2007). The *incompleteness of arithmetic* proves that we cannot construct an axiomatic system from which we can deduce all the propositions valid in arithmetic.

Moreover, from the incompleteness of arithmetic, it is deduced that we cannot prove the consistency of arithmetic from within the arithmetic. That is to say, in order to prove the consistency of arithmetic, we need to be supported by another metatheory external to arithmetic, whose consistency we must also presuppose.

Pluralism in the conception of mathematics

When the program of Hilbert entered a crisis, the classical conception of mathematics also entered a crisis. There are other conceptions of mathematics such as the intuitionist/constructivist, which have a stricter attitude and only admit propositions effectively proved as valid (Hawking 2005). Outstanding among the constructivist mathematicians is the Dutch mathematician *L. E. J. Brouwer (1881–1966)*.

► **Pluralism** has been extended to the same conception concerning what the mathematical objects are. Set theory is not the only possible

description of the mathematical objects. The concept of category appeared as a basic description of mathematical objects; categories are not based on the concepts of sets and belonging but on the concepts of function and composition.

3. Third phase. The formalization of the processes

In his paper in 1936 (Turing 1936–1937), *Alan Turing (1912–1954)* presented his exact formalization of the concept of “effective method” called the *Turing machine*. *Alonzo Church (1903–1995)* (Church 1936) had presented another different formalization of the algorithms some months previous to Turing (Church 1936). The formalization of Church is called *the lambda calculus*. The formalization of the Turing machine and the lambda calculus turned out to be equivalent in the sense that both described the same set of algorithmic procedures or functions.

Once the mechanism of his machine was formally established, Turing obtained a surprising result which strengthened the theorem of incompleteness of Gödel (Turing 1936–1937). Turing proved that it is not possible to decide in all cases whether a given program will stop or not. Reasoning on the Turing machine, a version of the incompleteness theorem of Gödel can also be proved.

The ideas of Church and Turing are at the core of current theoretical computing (Davis 2000). Moreover, the applicability of computing has decisively affected the development of the applied dimension of the formal sciences. It has highlighted applied dimensions, unknown until now, of languages and formal models such as pragmatism, experimentation, implementability, and efficiency. This has led to the plurality of logics, suited to several finalities. The existence of a plurality of logics opens up new perspectives for scientific language as each of these reflects a partial dimension of reasoning.

The Risk of Committing Errors

The innovation brought about by the theorems of undecidability and incompleteness is that we are

faced with risk in the very environment of formal sciences, where we can exercise most control over our knowledge. Precisely because this risk of committing errors is based on the very nature of the formal processes, there is no formal explanation which tells us how we have to assume this risk.

Formal Sciences, Metaphysics, and Theology

Formal reasoning transcends all languages and all levels of human knowledge, including the metaphysical (Salmon 2005) and religious. The formal development of mathematics throughout the twentieth century proved that the results of mathematics cannot be complete, and therefore, they are open to several possibilities which cannot be predetermined in all cases.

Between formal sciences and metaphysics, there is a paradoxical link. On the one hand, formal sciences and metaphysics are two opposite dimensions of human knowledge with considerable differences between the two. On the other hand, there are some deeply rooted similarities between metaphysics and formal sciences.

Why the world is intelligible, why the world exists, and why goodness exists. These are metaphysical questions because they do not ask the reasons or causes behind how we understand the world, rather why these reasons and causes exist. Metaphysical statements answer these questions referring to views about the world as a whole.

Formal sciences are about a formally defined language. Empirical sciences are inevitably particular disciplines as they refer to an aspect of the world. Metaphysics is essentially transdisciplinary, as it refers to the reality as a whole.

Theological statements are metaphysical statements that express views about the world in relation to God from religious foundations. Religious communities use theological symbols to explain how God reveals himself to human beings. The revelation of God answers questions presented to man by metaphysics: the full

meaning of life, the creation and existence of God, and his revelation to the world. By reasoning about empirical experiences, we do not deduce statements about the revelation of God.

Religions present God as the ultimate foundation of reality. Theological reflection cannot avoid its relationship with metaphysical reflection as both ask about the ultimate questions of reality. Different ways of understanding theological reflection correspond to different metaphysical conceptions of reality.

Metaphysical and theological arguments need to be able to span different cultural communities. Formal reasoning can fully span communities, and it forms the basis for interdisciplinary, intercultural, and interreligious communication.

Mathematics, Modern

Javier Leach

Facultad de Informática, Departamento de
Sistemas Informáticos y Programación,
Complutense University of Madrid, Madrid,
Spain

The third epoch of the historical evolution of mathematics began in the seventeenth century and extended to the end of the nineteenth century. In this epoch, there appeared a new relationship between mathematics and the empirical sciences when mathematics was used as a *language* to express the laws of nature (Heilbron 2003; Olby 1996). Mathematics was used in the first place as the language of physics and then as the language of other empirical sciences such as chemistry, biology, etc., and in the twentieth century, this was extended to sciences which included human conduct such as the economics, sociology, etc.

Mathematics as a Language of Science

Before the modern age, possibly the most well-known treatise for the study of natural phenomena was the *physics* (the text on the physics of Aristotle can be found at <http://classics.mit.edu/Aristotle/physics.html>) of Aristotle (Leach 2010). The works of Aristotle were translated from Greek and were known widely in Europe, to a large extent thanks to Islamic philosophers and mathematicians such as *Avicenna* (980–1037), *Avempace* (1080–1138), and *Averroes* (1126–1198).

Galileo Galilei (1564–1642) represents the change which took place in the world of science at the beginning of the modern age. The scientific work of Galileo was characterized by the use of instruments to observe nature and by the use of mathematical language.

The new physics brought about by Galileo differed from the physics of Aristotle in the use it made of quantitative measurements, expressible in mathematical language, and in the use of new

observation instruments, such as the telescope. Instead of quantitatively describing physical phenomena, the physics of Aristotle explains why these occur through speculation on their causes. In particular Aristotle distinguishes four types of causes: material, formal, efficient, and final (<http://classics.mit.edu/Aristotle/metaphysics.5.v.html>).

On using mathematics as language, the differences between the causes do not come from language but only from differences in the empirical observations on which the causal (Bunge 2008) study is based. For example, there are physical, biological, or social type causes because there are physical, biological, and social observations. However, within physics, biology, and the social sciences, the causes are expressed uniformly through mathematical laws.

In modern science both mathematical formulation and empirical observation are important. In fact, modern science arose from the ingenious combination of both. Quantitative observation is supported by two extremes in tension: observational experience and mathematical language.

The study of causes is a central component of scientific study. The expression of causes in mathematical language is at the root of the richness and the limitations of modern science. The distinction of four types of causes made by Aristotle is not based on the description of how things “behave” but on the interpretation of what Aristotle believed things “were.” This led Aristotle into committing serious errors in the description of the conduct of things. For example, Aristotle believed that if a body weighed more than another, it would fall more rapidly as he considered that the weight of the body was caused by the inclination of every body to tend to occupy the place corresponding to it by its very nature.

The Autonomy of Modern Science

The autonomy of modern science is a consequence of the quantitative observational method. The knowledge of the laws of nature no longer depends on the authority of a philosophical or religious theory but only on the methodical observation of nature and the mathematical formulation of the laws observed.

The autonomy of science as regards ► **meta-physics** and religion arose from the separation of mathematical language based on formal signs used to express the data observed and the metaphysical language based on symbols proper to metaphysics and religion. The basic components of the language of science are signs, which have formal, precise, and delimited meaning. However, metaphysics and religion make use of symbols which refer to the ultimate meaning of the totality of the world and to the transcendent and which cannot be reduced to quantitative signs.

Historically, the changes in the scientific view of the world have always affected the religious views of the world. Nevertheless, the change that occurred with the incorporation of modern science was especially important because modern science is by its own methodology independent of religious knowledge. Since the modern era, the autonomy of science has led to a new relationship between the scientific view of the world and the religious view being at times conflictive and at other times a factor for encounter and mutual interaction.

Mathematics and Metaphysics in the Modern Era

In the modern era, mathematics underwent a new internal development when it became the language of the empirical sciences. At the same time as this transformation of mathematics in the modern era, new basic metaphysical-type beliefs appeared. I will focus on three of these: *the principle of sufficient reason*, *causal determinism*, and *the rejection of* ► **metaphysics**.

The Principle of Sufficient Reason

The principle of *sufficient reason* (Pruss 2006) attributed to *Gottfried Wilhelm Leibniz* (1646–1716) established that no phenomenon occurs in nature which does not have a sufficient reason which explains it. The principle of sufficient reason is equivalent to the affirmation that a being that knows all the causes will be capable of explaining why all that is occurring occurs. Given that modern science understood a cause or reason to be

a mathematical reason, the principle of sufficient reason seemed to imply fatalist mathematical determinism.

The principle of sufficient reason supposed that any fact could be explained. This went against the possibility of free choice. In order to salvage the freedom of the human being, Leibniz distinguished between the limited knowledge of man which enables him to take decisions freely because he does not know all the causes of things and the unlimited knowledge of God who knows all the causes or reasons (G. W. Leibniz, *Discourse on Metaphysics*: <http://www.anselm.edu/homepage/dbanach/Leibniz-Discourse.htm>).

For Leibniz nothing in the world was indeterminate; everything followed a plan which was clear in the mind of God, and through this, God had created the best possible world. Leibniz believed that all the aspects of the world, both natural and supernatural, are related by links which can be discovered through rational methods. From this perspective, Leibniz thought that in order to discuss any problem with a man of “good will,” it was sufficient to formalize the problem, and both said “let us make the calculations” (*The Art of Discovery* 1685). These calculations had to be supported by some type of logic. However, although Islamic and scholastic philosophers had achieved some developments of the work of Aristotle, in the middle of the seventeenth century, formal logic was basically as it had been left by the Greeks.

Causal Determinism

Causal determinism is another consequence of the metaphysical belief that everything has a mathematical explanation. It is sufficient that everything has a mathematical explanation so that everything might have a cause or a *raison d’être*. Likewise we can say that if everything has a mathematical explanation, everything would be deducible from certain basic mathematical propositions. A characteristic representative of causal determinism was *Pierre-Simon Laplace* (1749–1827) (Laplace developed Newton’s mechanics; Laplace’s equations are important, as is his partial differential equation). Laplace believed in causal determinism. Laplace believed

that, just as Newton's laws could predict astronomical phenomena, all phenomena could be predicted using the location and momentum of the atoms making up matter. Laplace explained his determinist view by saying that if there were a demon that knew the position and momentum of all the atoms in the universe at any given moment, this demon would be able to predict all future events using Newton's equations.

The Rejection of Nonempirical and Nonmathematical Knowledge

The fact of denying the possibility of metaphysics is in itself an act which falls within metaphysical activity. Metaphysical activities refer to the knowledge of the essential, what finally matters, the definitive. Throughout all the cultural history of humanity, there has appeared the question regarding the possibility to know the essential in different ways. It is a question which is common to all cultures and to all religions.

Experimental observation, measured, quantified, and formulated with formal and methodical precision, is the center of modern science. Experimental knowledge of the facts and mathematical reasoning appear at the roots of scientific knowledge. Do our senses only perceive quantifiable experiences? Apart from scientific experience, is there also a metaphysical vision of the reality? Does quantifiable knowledge exhaust human knowledge? The negation of these questions is a metaphysical act in itself. The rejection of nonempirical and nonmathematical knowledge is a metaphysical act in itself.

Description

A summary of Maya religion must underscore the varied nature of the ideas and practices that make it up. This variation can be attributed to three causes: first, there is no overarching institutional structure; second, until recently, the religion has been based exclusively in an oral tradition; and third, the ritual specialist depends on his or her own observations and revelations in the elaboration of ritual and ceremony. In spite of its great variety, some common themes and practices emerge across the many regions where the Maya live and practice their traditions, namely, Mexico, Guatemala, Belize, El Salvador, and Honduras.

In recent decades, Maya religion has become an important facet of the "Maya Movement," sometimes referred to as the "pan-Maya movement" (Soto and Ricardo 1995; Molesky-Poz 2007). This movement is an attempt by indigenous scholars and activists to bring a greater cultural and political unity to Maya peoples. As an expression of identity and culture, Maya religion has come to play an increasingly public role. This is an especially significant change since during various times in history the ritual specialists of the Maya were forced to practice in secrecy and to clothe some of their most powerful symbols in

Christian imagery to avoid persecution by the colonial powers of church and state.

The Catholic Action movement of the 1950s and the Guatemalan Civil War (1960–1996) dealt significant blows to the Maya and their religion. The rapid growth of evangelical Protestantism throughout these same areas during the last few decades also marginalized Maya ritual practices. Whereas Catholicism and Maya religion forged an uneasy alliance for many centuries, Protestantism has been more exclusive in its demands that its adherents eschew all other ritual activity. That the religious practices of the Maya continue to flourish is an important statement in the face of 500 years of colonial pressures.

Self-identification

Science

The Maya have a number of traditions they consider to be specialized bodies of knowledge which could be labeled as sciences. Much traditional medicine would fall under this category, as would astronomical/astrological knowledge. But Maya religion is more of an intuitive set of practices and beliefs. Emotions and other forms of embodied cognition play a more central role in this tradition than do analytical and abstract rationality (Hart 2008; Molesky-Poz 2007; Tedlock 1992). That being said, a strong current of inductive logic seems ever present in Maya religion which has led to an especially rich set of divinatory and oracular techniques. Through careful observation of phenomena and association of past with present, Maya ritual specialists have developed elaborate associations between what they perceive to be related causes and effects.

Religion

In a sense, Maya ritual activity cannot be a religion as there is no word for religion in most Mayan languages. However, the ritual practices that the Maya utilize bear a “family resemblance” to activities performed by many cultures to mediate between themselves and the invisible forces that are thought to influence so much of human life. European ideas about

institutional religions and scholarly dichotomies that promote a division of the sacred and the profane or the natural and the supernatural do not fit well into Mayan worldviews.

Characteristics

The Maya often visit caves, mountain tops, and lakes to perform rituals. Crosses and orientation to the four cardinal directions are important in this tradition. Maya religion relies on an ecological worldview; the Maya envision themselves as embedded in an extended community which includes plants, animals, space, time, and numerous invisible forces such as the ancestors of their traditions. It is thought that certain places come to be imbued with special energies from previous use and from the presence of particular Nawales, spirits or energies that support existence. The 260-day ritual calendar known as the Cholq’ij is a combination of 20 Nawales (days) and 13 numbers (Rupflin-Alvarado 1995). This calendar plays a key role in many religious practices including the Ceremonia Maya (Fig. 1), a ritual (common in Guatemala) celebrated around a ceremonial fire that includes prayers, purification, and the invocation of all 260 days of the Cholq’ij. The Cholq’ij is also a basis of many divinatory practices. For the sake of clarity, Nawal means the name for the “day lords” that govern each of the twenty days of the Cholq’ij. But the term is also used as a more general term for the spiritual forces and energies of a place or of a being. It has been said that “everything has a Nawal.”

Relevance to Science and Religion

Maya religion has always shown a deep interest in natural phenomena and in such fundamental topics as space and time. The centrality of calendars and the careful observation of the heavens have always played a central role in Maya religion. These same topics end up as important ones in European scientific traditions; science (profane) and religion (sacred) were never

Maya Religion,**Fig. 1** Ceremonia Maya
(Photo by author 2008)

separated in Maya culture in the way that they were in European culture. The highly practical and the mythological have always been fused in Maya religion.

Sources of Authority

The chief authorities in Maya religion are the ritual specialists who conduct ceremonies and practice curing. The highland Maya of Guatemala typically use the term *Ajq'ij* for these specialists. This term can be translated as “day person” or “sun person” and refers to the specialist’s knowledge of the *Cholq'ij*. A less common term among these same groups is *Chuchqajaw*, which means “mother-father” and imbues the specialist with the authority of the ancestors. In certain places in the Guatemalan highlands, such as Momostenango, the *Chuchqajaw* serves as a higher authority than the *Ajq'ij* (Tedlock 1992). In the Yucatan peninsula, the ritual specialists are typically referred to as *J'meen*, translated as “doer” (Thompson 1970). There is also another ritual specialist called *J'k'iin* (“sun person”) in the Yucatan peninsula. This person is often considered to be of

higher authority than the *J'meen*. Among the highland Maya of Chiapas, the term *J'ilol* (“seer”) designates the ritual specialist.

Ritual specialists gain authority from esoteric knowledge, such as an extensive understanding of the meanings and prognostications of the *Cholq'ij*, from being born on special days, from unusual signs during their birth (such as being born with a caul), from revelations in dreams and oracles, through apprenticeship to a ritual specialist, and through the knowledge and capacity to heal using rituals and plant remedies.

An additional source of authority for Maya religion comes from the *Popol Vuh*, a text of the K'iche' Maya of Guatemala written down in the early eighteenth century from a corpus of much earlier oral accounts (Tedlock 1996). The *Popol Vuh* is composed of historical material, genealogies, and extensive mythological accounts including a creation story. Many contemporary prayers draw from this text.

Ethical Principles

Family unity is central to the ethical principles of this tradition. From family unity, an ethic of respect

and reciprocity ensues so that elaborate covenants and duties have come to exist between children and parents, humans and nature, individual and community, and the living and the dead. This background of reciprocity leads to complex notions of equilibrium and harmony between the elements that sustain life. Whatever is received must be reciprocated in some fashion; many of the rituals are based on this principle (Vogt 1993). If a person develops an illness, some fault or misstep is often inferred, and a “paying of one’s debts” to the gods and ancestors follows (Soto and Ricardo 1995). Similarly, if a person has a particular desire, he or she may present a ritual offering and expect some reciprocation from the same powers. A common supplication in the Ceremonia Maya is the giving of thanks for one’s life and livelihood with the understanding that this is always an ongoing debt that requires offerings and continual gratitude.

Key Values

Maya religion promotes family unity, community solidarity, responsibility, education, respect of elders and of the dead, ritual duties and commitments, marriage, work, and the respect of nature (Soto and Ricardo 1995). A strong reliance on and respect for the extended community informs all values for the Maya.

Conceptualization

Nature/World

Many nonhuman things or objects can be related to as sentient and alive in Maya religion (Watanabe 1992).

Human Being

Human life is sustained by a complex web of covenants between children and parents, humans and nature, individual and community, and the living and the dead.

Life and Death

According to the Popol Vuh, human beings were made from corn in order to offer thanks

and sustenance to the gods (Tedlock 1996). There is significant continuity between life and death in Maya religion. Sometimes, this is explained in terms of individual souls being present as guardians and intercessors for their descendants; otherwise, personal existence takes on more of an essentialized manifestation after death (one merges with the “ancestors”). The dead are regularly invoked and remembered during important events, especially in ritual activities.

Reality

In Maya religion, humans have access to reality through their senses and through intuition and conscience. But everything that participates in this reality is not visible. Important agents in the ritual ecology often communicate through extraordinary channels, such as through divinatory signs.

Knowledge

For the Maya, knowledge comes from tradition, from revelation, and from experience.

Truth

Truth is best arrived at through careful observation and long-term experience. For this reason, elders are thought to be key sources of reliable knowledge.

Perception

Maya religion emphasizes the importance of the five senses and also some additional channels of information such as intuition and conscience. Many nonhuman entities (plants, animals, the dead) are thought to use the same set of senses.

Time

Time plays a key role in Maya religion, and multiple calendars are kept with careful accuracy. The Cholq’ij plays an especially important role in Maya religion and delimits various aspects of personal and collective destiny.

Consciousness

The Maya value numerous states of consciousness. In addition to “normal, waking consciousness,” dream experience is thought to be especially

revelatory. Many of life's most important lessons come though dream experience.

Rationality/Reason

In Maya religion, rationality and reason play a role but are no more significant than intuition and sudden flashes of insight. Whereas rationality and reason are often exclusive and analytical, Maya religion tends to be more holistic and tolerates a great deal of ambiguity (Hart 2008). "Both/and" seems to be more central here than does "either/or."

Mystery

Mystery is a common theme in Maya religion, and legends abound in this tradition. Encantos (enchanted places, places where mysterious things occur and where magical beings often make an appearance; literally "enchanted place.") are thought to be especially mysterious; stories are often told about people disappearing into the centers of hollow mountains and living for years only to reappear with elaborate tales of their experiences in these other worlds (Hart 2008; Molesky-Poz 2007). Magical beings such as red dwarves or talking animals often appear in these legends (Tedlock 1992). Some people are also given Secretos by these beings or through their own dreams. These Secretos may allow them to breathe underwater, fly, or possess some other superhuman ability.

Relevant Themes

The Maya have consistently shown a deep respect for their ecology and for all the beings that compose it. This enduring interest and reliance on their supporting ecology has produced sophisticated knowledge of plants, animals, and other natural phenomena. Because there is little division between this world of nature and the invisible world of forces and energies, Maya religion has imported a uniquely ecological sense into its practices. Systematic observation, the use of inductive logic, and the amassing of data could apply equally well to many

forms of science and to Maya religion. Moreover, both attempt to provide people with some measure of understanding and control in an uncertain world.

Description

The concept of (linguistic) meaning has attracted an enormous amount of attention in contemporary philosophy. In order to clarify this concept, philosophers have proposed so-called theories of meaning. Theories of meaning can be understood as explanatory accounts of what has been variously described as “how meaning arises,” “wherein meaning consists,” “how meaning is determined,” and suchlike. The value of a correct theory of meaning has, by some theorists, been taken to consist simply in its contribution to an understanding of the workings of human language, but has, by other theorists, also been taken to consist in its potential for clarifying important philosophical problems, for example, by providing a means for distinguishing between words and sentences that have real or genuine meaning and words and sentences that do not have real or genuine meaning but are, in effect, nonsense.

Theorists of meaning typically propose one or several explanatory concepts intended to shed light on meaning. In what follows, we will survey some of the major proposals of such concepts, along with some of the consequences that these proposals have or have been taken to have. Our survey will focus primarily on proposals that have been developed within the tradition of analytic philosophy, where investigations into theories of meaning have been particularly intense.

Two Classical Approaches

The starting point of much modern theorizing about meaning has been traditional philosophy’s theorizing about meaning, and it is therefore appropriate to begin by taking a look at some traditional philosophical approaches to the subject. Two influential such approaches can be found in the writings of the classical philosophers Plato (429–347 B.C.) and Aristotle (384–322 B.C.).

In Plato’s writings, there is a clear tendency to understand the meanings of words – in particular, nouns and verbs – in terms of nonspatial, nontemporal, objective ideas (*eidos*), which are taken to exist in a suprasensible realm accessible to the mind but not to the senses. In line with this, to grasp the meaning of a word is regarded as amounting to a grasp of the nonspatial, nontemporal, objective idea with which the word is correlated. This way of understanding the meanings of words is usually referred to as “Platonism” or “concept realism.”

An alternative approach to meaning is found in Aristotle. In Aristotle’s *De Interpretatione*, for example, words – or at any rate, nouns and verbs – are said to have meanings in the sense that they function as symbols for “images” (*semeia*) “in the mind” (*en te psyche*) (1962, p. 114). These mental images, says Aristotle, are the same for the whole of mankind, whereas the words that symbolize them typically differ from language to language and are established by convention.

A major difference between Platonist and Aristotelian approaches to meaning is that whereas the former explains meaning via appeal to the mind’s apprehension of nonspatial,

nontemporal, objective ideas existing in a suprasensible realm, the latter explains meaning via appeal to mental images existing in the mind. A major advantage of the Platonist approach over against the Aristotelian approach is its capacity to account for the commonsensical belief that a word can have the same meaning for several distinct individuals (which would seem to require that meanings are in some sense independent of individual minds), whereas a major advantage of the Aristotelian approach is its capacity to account for the equally commonsensical belief that human beings can individually or collectively somehow come up with new meanings for words (which would seem to require that meanings are in some sense dependent upon human minds). A common feature of both Platonist and Aristotelian approaches to meaning, however, is the basic idea that language use is basically a matter of articulating meanings that are apprehended by the human mind.

The above basic idea dominated much of subsequent Western thinking about meaning and can be found in one form or another in the work of medieval scholastics such as Thomas Aquinas, in early modern philosophers such as René Descartes and John Locke, and in the work of early twentieth-century analytic philosophers such as Gottlob Frege (1848–1925) and Bertrand Russell (1872–1970). Thus, in Frege’s famous essay “Der Gedanke” (1918), we find a variant of a Platonist theory of meaning, and in Russell’s famous essay “The Philosophy of Logical Atomism” (1918), we find a variant of an Aristotelian theory of meaning. Frege holds that words and sentences are associated with meanings existing in a nonspatial, nontemporal dimension called “the third realm” (*das dritte Reich*) (1918, p. 69), whereas Russell holds that the meanings of words and sentences are “always more or less psychological” (1918, p. 506). Frege and Russell are in agreement, however, as to the correctness of the basic idea that language use is ultimately a matter of expressing the content of one’s thoughts in the garb of words and sentences.

The above basic idea was soon replaced by very different ideas about meaning in mainstream analytic philosophy, theories which take as their

explanatory concepts neither variants of Platonic ideas or Aristotelian images nor thought contents more generally, but instead, such concepts as “verification conditions,” “human behavior,” “speaker’s intentions,” “truth conditions,” and “rule following.” We turn now to survey some of these alternative accounts. These alternative accounts have often been motivated by an ambition to account for meaning without presupposing an underlying mind-body dualism of the sort that can be seen to figure in Platonist and Aristotelian approaches and, more generally, to provide an account of meaning that fits into an antimetaphysical and nonmentalistic view of the world.

Verification Conditions

According to some of the logical positivists of the 1930s and 1940s, the meanings of words can be explained via the meanings of the sentences in which the words occur, and the meanings of sentences – or at any rate declarative sentences – are said to consist in their *verification conditions*. Thus, Moritz Schlick (1882–1936), in his programmatic paper “Meaning and Verification” (1936), claims that “The meaning of a proposition is the method of its verification” (1936, p. 341). The verification conditions of a declarative sentence can be specified as those empirical observations that count as confirmation of the sentence.

The logical positivists often claimed that their theory of meaning accorded with science. Scientists were said to understand the meanings of scientific sentences in terms of verification conditions, and this was taken to provide a prototype for how declarative sentences in other contexts should be understood as well.

In more recent times, verificationist theories of meaning have gained renewed interest through the work of the Oxford philosopher-logician Michael Dummett. In various papers republished in *Truth and Other Enigmas* (1978), Dummett argues that the currently most defensible theory of meaning is a theory according to which “to know the meaning of a statement is... to be capable of recognising whatever counts as verifying the statement” (1978, p. 227).

Verificationist theories of meaning have often been taken to have radical consequences for traditional philosophical problems. The logical positivists, in particular, thought that this sort of theory gave them good reason to reject much of metaphysics and theology as nonsensical, inasmuch as the sentences of metaphysics and theology were taken to often lack verification conditions and therewith meaning.

There are several widely recognized problems with verificationist theories of meaning, however. One such problem is that for many declarative sentences, there are often various different sorts of empirical observations that count as confirming them, which would seem to require on verificationist premises that the sentences have various meanings corresponding to the different verification conditions. This seems wrong, however: a sentence such as “the Earth is not flat” can be confirmed in numerous ways, but it would seem wrong to conclude from this that it has correspondingly many meanings. For these and other reasons, many philosophers have considered verificationist theories of meaning unconvincing.

Human Behavior

A different theory invokes *human behavior* to explain meaning. A main philosophical representative of this approach is W.V.O. Quine (1908–2000). In *Word and Object* (1960), Quine proposes that the meaning of a declarative sentence should ultimately be understood on the basis of “men’s dispositions to respond overtly to socially observable stimulations” (1960, p. xi). Like the verificationist theory of meaning, the present theory has been taken to draw support from science. In Quine’s view, science has developed steadily toward a naturalistic worldview, and a naturalistic worldview fits ill with the recognition of seemingly nonmaterial phenomena such as ideas, meanings (construed as mental entities), and suchlike. The proper scientific thing to do, from a naturalistic point of view, is to do away with these spurious entities and instead seek to explain meaningful sentences in terms of responses to empirical input in line with the behaviorist stimulus-response schema.

An interesting consequence of the present behaviorist theory of meaning is that there will always be an element of indeterminacy as to whether two speakers use the same orthographically or phonetically identified word in the exact same sense, for sameness of sense must here amount to something like consistency of behavior, and there is always more than one way in which one person’s behavior can be consistent with another person’s behavior. A similar result holds also with regard to the translation of a word from one language into a word from another language: there is always an element of indeterminacy as to whether a translation is fully adequate or not, for the behavior associated with a word in one language will always be consistent with the behavior associated with a variety of different words in another language. This result is sometimes referred to as the indeterminacy of translation thesis.

Behaviorist theories of meaning of the present sort face some well-known difficulties. One pressing difficulty, pointed out by various cognitive scientists, derives from children’s language learning. Behaviorist theories of meaning would seem to require that children learn language via meticulous observation and copying of the behavior of other humans in response to verbal input, in line with the behaviorist stimulus-response schema. This does not appear to be the case, however. Children typically learn language by casual observation of the language usage of others and, moreover, quickly acquire an ability to freely and creatively construct and express sentences that they have not previously learned from anyone or have not observed others respond behaviorally to, but which nevertheless are perfectly meaningful. These circumstances have been regarded by many to be unaccountable for along behaviorist lines and have accordingly led many to reject behaviorist theories of meaning as untenable.

Truth Conditions

A further theory has been put forth by Donald Davidson (1917–2003) in his programmatic paper “Meaning and Truth” (1967) and makes use of the notion of *truth conditions*.

Like behaviorist theories such as Quine's, Davidson's theory makes no use of spurious nonmaterial entities such as ideas, meanings (construed as mental entities), propositions, and suchlike. But contrary to Quine, Davidson does not invoke behavior as an ultimate explanatory concept in the theory of meaning. Instead, he invokes the concept of truth or truth conditions.

One of Davidson's starting points is the claim that the concept of truth is among the clearest concepts we have. We typically know, without prior philosophical theorizing, what it would mean for such-and-such a sentence to be true, that is, what the sentence's truth conditions are. Given this, Davidson proposes that we use the concept of truth to explain the meaning of a declarative sentence: the meaning of a declarative sentence *s* is said to be "given by" the conditions that must be obtained for *s* to be true. Thus, Davidson suggests the following schema as a means for giving the meaning of any declarative sentence *s*: "'*s*' is true if and only if *p*," where *p* represents the occurrence of *s* without quotation marks and is taken to yield the truth condition of *s* (1967, p. 309). The typical example is: the meaning of the sentence "Grass is green" is given by the phrase "'Grass is green' is true if and only if grass is green."

Among the advantages of the above method of explanation, as Davidson sees it, is that it explains meaning without invoking obscure mental entities of any kind. Another advantage is that it replaces the equally obscure "means that" locution in meaning-explanations by the much clearer logical biconditional "if and only if."

Davidson's theory of meaning has spurred a lot of discussion, both sympathetic and critical. One interesting criticism of the theory is that by "giving" the meaning of a declarative sentence by specifying its truth conditions, the theory is not really explaining how meaning arises or wherein it consists or how it is determined. We are told *what* the meaning of a given declarative sentence is but not how the sentence has come to have that meaning in the first place. Provided that theories of meaning are to tell us not merely what meanings sentences have but also how they come to

have these meanings or wherein the meanings consist or how the meanings are determined, this criticism might amount to a major blow to Davidson's theory. Apart from this, however, the theory will have to be worked out so as to provide some way of explaining also the meaningfulness of parts of language to which the truth predicate does not obviously apply, such as commands, questions, and so on. Many have pointed out that it is not obvious how this is to be done.

Speakers' Intentions

We turn next to a theory that fastens on the notion of *speakers' intentions* (or just *intentions*). The prototypical theory of meaning of this sort is due to Paul Grice (1913–1988) and is put forth in his programmatic paper "Meaning" (1957). In what follows, we will take Grice's paper as representative of theories of meaning of the present sort.

Grice starts by distinguishing between "natural meaning" (as in "Those spots mean measles") and "nonnatural meaning" (as in "The remark 'Smith couldn't get on without trouble' means that Smith finds his wife indispensable") and makes it clear that his theory of meaning seeks to account for the latter sort of meaning (which he indicates by inserting the index "_{NN}" after "means," as in "means_{NN}"). Grice's basic proposal is to take a locution such as "A meant_{NN} something by *x*" – where "A" stands for a speaker and *x* for some expression – as roughly equivalent to "A intended the utterance of *x* to produce some effect in an audience by means of the recognition of this intention" (1957, p. 384). This proposal equates "means_{NN}" with "intends" and understands meaning or intention as a sort of relation between a speaker and an audience.

Intention-based theories of meaning of the present sort naturally lead to a rather liberal view of language usage. If a speaker intends to use a word or sentence to produce some effect on an audience by the recognition of this intention, then that is what the word or sentence means, plain and simple.

An initial problem with the above sort of intention-based meaning theory is that it seems to ignore that words and sentences can be meaningfully uttered even in the absence of an

audience, for example, in solitary discourse. Grice seeks to solve this problem by introducing the notion of a *possible audience*: an expression x means_{NN} something if it is at least intended to produce some effect *had there been* an audience present.

A more serious problem with the present theory is that it seems to ignore that words and sentences can mean things entirely different from the effect they are intended to have on audiences by means of the recognition of this intention. A famous counterexample goes like this: an American soldier taken captive by the Italians in World War II utters the German phrase “Kennst du das Land, wo die Zitronen blühen?” intending hereby to effect the Italians to believe that “I am a German officer.” Irrespective of the American soldier’s intentions, however, the utterance does not mean “I am a German soldier” but (in English translation) “Knowest thou the land where the lemon trees blossom?”

Various attempts have been made to overcome the above and similar problems while preserving the notion of intention as a key explanatory concept in the theory of meaning. Far from all, philosophers have found these attempts convincing, however, and many have concluded that intentions ought to be assigned some less central role in the theory of meaning, for example, serving the function of selecting between possible alternative meanings in cases of linguistic ambiguity.

Rule Following

An explanatory concept associated with the work of the later Ludwig Wittgenstein is that of *rule following*. Behind the idea of rule following lies the idea that the meaning of a word can in most cases be said to consist in its *use*. As Wittgenstein says in a famous passage in the *Philosophical Investigations*, “For a *large* class of cases – though not for all – in which we employ the word ‘meaning’ it can be defined thus: the meaning of a word is its use in the language” (1953, §43). This idea does not entail that words can be used in whatever arbitrary way one chooses, however, for words, or at any rate meaningful words, are used in accordance with what

Wittgenstein calls “rules,” “techniques,” or “customs” (1953, §199). To learn the meanings of the words of a language is to learn the rules, techniques, or customs associated with the uses of the words. This is roughly what is meant by “rule following.”

There are numerous rules at work in a language. New rules are constantly being added, and old rules are constantly falling out of use. There are rules associated with such things as the application of color words such as “green” and “brown,” rules associated with the use of sentential connectives such as “or” and “not,” rules associated with mathematical and scientific terms such as “plus” and “mass,” rules associated with religious terms such as “God” and “sin,” and so on and so forth. Wittgenstein characterizes the various practices in which different rules are at play as different “language-games” (1953, §7) or “forms of life” (1953, §23). There is no meaningful use of words, he holds, that is not rooted in some sort of language-game or form of life.

Philosophers sympathetic to Wittgenstein’s approach to language often claim that Wittgenstein did not seek to develop any theory of meaning, but simply sought to remind us of things about our language usage that we already in some sense know and take for granted. Even if this claim is correct, it is nevertheless the case that Wittgenstein’s approach, if correct, entails that various philosophical accounts of meaning are mistaken.

Wittgenstein’s approach to meaning has attracted both enthusiastic support and thorough criticism. Some critics of the approach have argued that the approach’s underlying idea, that the meaning of a word consists in its use, cannot be right, for the use of a word requires an antecedent understanding of the sense in which it is to be so used, in which case, sense would seem to precede use. Another line of criticism of the same underlying idea is that whereas uses of words can be popular, unpopular, and suchlike, the senses of words are not the sort of things that are capable of being popular, unpopular, and suchlike, in which case the sense or meaning of a word must be something very different from its use.

Deep Structures

Several of the meaning theories surveyed in the last few sections have largely been developed in an antimetaphysical and nonmentalistic spirit. From roughly the 1960s and onward, there has been a growing conviction among some influential theorists that these sorts of accounts are inadequate, however, and that some more substantial metaphysical and/or mentalistic premises are needed in order to account for meaning. One well-known such theorist is Noam Chomsky.

Although some of Chomsky's basic ideas on meaning can be found already in traditional approaches to meaning of a Platonistic or Aristotelian sort, Chomsky has chosen to characterize his approach as "Cartesian" on account of the stress he lays on the notion of "innate abilities," a stress familiar from the work of Descartes and other rationalist epistemologists.

One of Chomsky's basic ideas is that human beings have an innate ability to acquire and use language, much like birds have innate abilities to learn particular classes of songs, beavers have innate abilities to build dams, bees have innate abilities to integrate their behavior into the intricacies of a hive, and so on. Language use, on Chomsky's theory, is a matter of realizing this innate ability. Moreover, since the ability of human beings to acquire and use language is regarded as innate, it is also regarded as universal to mankind and, hence, not culture specific.

But how is this universalism to be reconciled with the fact that different peoples use different languages which differ not only in vocabulary but also in grammatical structure? Chomsky's answer to this question consists in positing what he calls a "deep structure" underlying the "surface structures" of the various contingent languages of the world. It is on the level of the deep structure of cognition that thought has its natural habitat and meanings are apprehended by the mind. However, in order to express meanings, speakers must ascend to the surface level of cognition, where the various contingent and acquired grammars of natural languages are to be found, and then clothe their thoughts in the

garbs of the words and sentences of that level. This all happens more or less unconsciously (see, e.g., Chomsky 1966, pp. 31–59.).

The chief strategy employed in arguing for the present theory consists in appealing to the rapidness and ease by which children pick up languages. This rapidness and ease is taken by Chomsky and others to be simply inexplicable in the absence of some sort of inborn and innate abilities on the part of human beings to acquire and use language.

An often-heard criticism of Chomsky's theory is that a satisfactory account of the "deep structure" allegedly underlying the surface grammars of natural languages has not yet been provided, in which case, the theory really only explains one unknown by another unknown and hence fails to explain anything.

Illocutionary Act Potential

Another recent theorist who has not sought to account for meaning along antimetaphysical or nonmentalistic lines is William P. Alston (1921–2009). Alston's theory seeks to explain meaning by identifying sentence meaning with *illocutionary act potential*. The theory makes heavy use of some ideas that go back to Oxford philosopher John L. Austin.

In *How to Do Things with Words* (1962), Austin distinguishes between locutionary acts, illocutionary acts, and perlocutionary acts. A "locutionary act," says Austin, is a use of a sentence whereby we "say something"; an "illocutionary act" is a kind of locutionary act whereby we perform some act "*in* saying something"; and a "perlocutionary act" is a kind of locutionary act whereby we produce some effect on ourselves or others in saying something (1962, pp. 99–101). The most important of these acts for present purposes are illocutionary acts, examples of which are urging, advising, ordering, protesting, stating, questioning, and suchlike.

Alston's initial idea is to identify the meaning of a sentence with its potential to figure in certain illocutionary acts: "What it is for a sentence to have a certain meaning is for it to be usable to perform illocutionary acts of a certain type"

(1987, p. 151). This does not mean that the contents of the illocutionary acts are identifiable as the meanings of the sentences used to make them, however. Rather, the contents of the illocutionary acts are *propositional contents* or *propositions* – the contents of thoughts – distinct from the meanings of the sentences by means of which these propositions are expressed. The sentence “The gate is open,” for example, has the potential of figuring in the illocutionary act of commanding someone to close a certain gate; this potential will count as the sentence’s meaning, but the content of the illocutionary act will be the propositional content of the command in view.

A problem with this initial statement of the idea – which Alston points out – is that one and the same sentence can often figure in a variety of different illocutionary acts, each of which has distinct propositional content. The sentence “The gate is open” can be used not only to command someone to close the gate, but also to inform someone that one’s garden gate is open, to proclaim that the gate of salvation is open, and numerous other things as well. Each of these illocutionary acts has distinct propositional content and makes different uses of the sentence “The gate is open.” The present theory would seem to require that this sentence has multiple meanings, each corresponding to one of the various illocutionary acts that can be performed by means of it.

Alston has a way of avoiding this problem, however. The problem is avoided by distinguishing between an illocutionary act *token*, that is, a particular occurrence of an illocutionary performance, and an illocutionary act *type*, that is, a type of illocutionary performance defined by its use of a given sentence to perform an illocutionary act. To every sentence – says Alston – there corresponds an illocutionary act type, which type can be used to make various different illocutionary acts, acts which in turn are typically differentiated from each other by features in the contexts in which the acts occur. The meaning of a sentence, says Alston, is to be identified not with any illocutionary act token but with the illocutionary act type by means of which

the various tokens are made. In line with this, Alston proposes the following more refined statement of the basic idea of the present meaning theory: “What it is for a sentence to have a certain meaning is for it to be usable to perform illocutionary acts of the matching type (that is, to have the matching illocutionary act potential)” (1987, p. 158).

Perhaps, one of the main difficulties with the above theory concerns how meaning-bearing illocutionary act types are to be identified and demarcated from the nonmeaning-bearing illocutionary act tokens with which they are matched. Take, for example, the sentence “the gate is open.” This sentence can be used in various illocutionary act tokens. But how is one to go about in seeking to determine objectively and nonarbitrarily what the meaning-bearing illocutionary act type is by means of which these illocutionary act tokens are made? If it is granted that the meanings of sentences are objectively determinable, the tenability of the present theory will seem to depend on the possibility of providing a satisfactory answer to this question.

Meaning and Metaphysics

Although much twentieth-century theorizing about meaning has, as we have seen, been pursued in an unequivocally antimetaphysical and nonmentalistic spirit, we have also seen that these sorts of approaches have been questioned in more recent years. The revival of metaphysics in contemporary Anglo-American analytic philosophy is likely to bring with it an increasingly strong interest in basically Platonistic or Aristotelian types of meaning theories in the years to come. Whether the traditional metaphysical or mentalistic theories of meaning will regain their former roles as central explanatory paradigms in the theory of meaning remains as yet to be seen. But in either case, it is clear that modern analytic philosophy’s widely endorsed ambition to account for meaning along antimetaphysical and nonmentalistic lines has proved to be much more difficult to realize than what was originally thought to be the case. Meaning, it seems, remains as difficult to account for as ever.

Mechanico-materialism

Carl Raschke

Department of Religious Studies, University of Denver, Denver, CO, USA

A general term used in the history of ideas to describe the view of the universe, including even life forms and social behavior that emerged from Newtonian physics in the late seventeenth century. Mechanico-materialism stresses the law-like regularity and “clockwork” precision in the operation of the identifiable components of physical reality. The metaphor of billiard balls zooming about a pool table is often used to capture the sense of what Newtonians characterized as a cosmos consisting of “matter in motions.”

Description

Mechanics is an area of physics that studies the motions of material objects. *Classical mechanics* is the part of mechanics that does not deal with theory of relativity and quantum theory. Although classical mechanics does not describe reality adequately for very large speeds or very small distances, it is an active area of physics, with important recent developments and

innumerable practical applications. Moreover, ideas that were first introduced within the framework of classical mechanics turned out to be very fruitful in many other areas of physics and in mathematics. The next sections will focus on the discussion of some of the important concepts of classical mechanics, presenting them in the chronological order of their historical introduction. A detailed account of the history of classical mechanics until the 1950s could be found in the monograph (Dugas 1955).

Pre-Newtonian Physics

The roots of classical mechanics are in antiquity. It flourished in ancient Greece, in particular, in the works of Aristotle (384–322 BC). Aristotelian scientific doctrines had profound influence on the scientific thought until the times of Galileo and Newton. Ancient scientists discovered some simple mechanical laws (e.g., the law of buoyancy), realized that the Earth had a spherical shape and were able to measure its radius.

The modern development of classical mechanics started in the 1400s and is usually associated with the name of Nicolaus Copernicus (1473–1543), who challenged the geocentric planetary system of Aristotle and Ptolemy (Claudius Ptolemaeus, c. 90–c. 168 AD). Free of the stifling influence of Aristotelian ideas, observational astronomy developed quickly, culminating in the experimental discovery of the three laws of planetary motion of Johannes Kepler (1571–1630). In the works of Galileo Galilei (1564–1642), René Descartes (1596–1650), and Christiaan Huygens (1629–1695), reliance on observational or experimental evidence were emphasized rather than pure reasoning.

Quantitative Period of Classical Mechanics

The foundations of our present understanding of classical mechanics were laid by Isaac Newton (1643–1727) in his magisterial treatise

Philosophiae Naturalis Principia Mathematica (“Mathematical Principles of Natural Philosophy”), originally published in 1686; see the annotated edition (Chandrasekhar 1995). Using the three laws of mechanics formulated in *Principia* together with his *law of gravitation*, Newton was able to derive the laws of Kepler.

To describe the rate of change of physical quantities, Newton developed differential and integral calculus (at the same time as, and independently of, Gottfried Leibniz (1646–1716)) – a mathematical theory of enormous importance. In Newtonian mechanics, the motion of an object is governed by ordinary differential equations that express its acceleration (the rate of change of its velocity) in terms of the mass of the object and the forces acting on it. The entire subsequent development of classical mechanics is based on the understanding of the mathematical structures behind Newton’s theory and its relation with other areas of mathematics and physics.

At the very foundation of Newton’s theory of mechanics are such fundamental concepts as *space*, *time*, *force*, *matter*, and *mass*. As it is not possible to discuss here these notions in depth, we only direct the reader to (Borchert 2006) and proceed to the post-Newtonian development of classical mechanics.

Variational Principles and First Steps toward Geometrization of Mechanics

Pierre de Fermat (1601–1665) showed that Snell’s law of refraction of light can be derived from the postulate that, when traveling from one point to another, a light ray follows the path that minimizes the travel time. Pierre-Louis de Maupertuis (1698–1759) suggested that in the realm of mechanical phenomena the situation is similar – namely, there exists certain quantity, called *action*, that is minimized in mechanical processes. He interpreted this as a manifestation of the wisdom of God, who does everything in the most efficient way. The vague (and mathematically incorrect) ideas of Maupertuis were put on a firm mathematical

ground by Leonard Euler (1707–1783), Joseph-Louis Lagrange (1736–1813), William Hamilton (1805–1865), and Carl Jacobi (1804–1851). Given the initial and the final configurations of the mechanical system (i.e., the initial and final positions and velocities of all particles constituting the system), the *variational principle* states that the evolution of the system between the initial and the final moments of time is such that the action of the system is extremal (i.e., minimal or maximal). The action is expressed through a function of time and of the positions and velocities of the particles which is called the *Lagrangian* of the system. From the fact that the evolution of the system is an extremum of the action, one can derive ordinary differential equations, called the *Euler-Lagrange equations*, governing the temporal evolution of the system. If one starts with the Lagrangian of a physical system, the corresponding Euler-Lagrange equations are the Newton's equations of motion of the system.

Lagrange's description of a physical system has several advantages over the description of Newton. For a physicist, writing down the Lagrangian is usually easier than writing down Newton's equations. The symmetries of the system (see below) are more clearly visible from the Lagrangian of the system rather than from Newton's equations. Most importantly, Lagrange's approach relies heavily on the geometry of the space of coordinates and velocities of the system.

Lagrange's formalism is especially useful if the system is constrained. A simple example of a constrained system is two point particles connected by a rod of constant length; the whole system is free to move in three-dimensional space. Since each particle has three coordinates, in the absence of the rod, the position of the system would be described by the total of six functions of time (giving all the coordinates of the particles at each moment of time). The rod, however, imposes the constraint that the distance between the particles should be the same at each moment. Because of this constraint, the position of the particles is described by only five functions of time.

Hamilton's Equations and Symplectic Geometry

Another big step in the interpretations of the laws of classical mechanics was their reformulation as the so-called *canonical equations* of Hamilton. Besides their inherent importance for solving concrete physical problems, these equations provided a completely new way of thinking about the geometry behind the dynamics of the system. In this formalism, the space where the evolution of a mechanical system takes place is the so-called *phase space* – a space of even dimension where half of the dimensions give the position and the other half give the corresponding *momenta* of the particles (in high school physics, the momentum of a point object is the product of its mass and its velocity, but the general definition of momentum is more complicated). Hamilton's canonical equations then imply that the phase space of a physical system is a *symplectic manifold*, that is, an even-dimensional space endowed with a special geometric structure called a *symplectic form*. The state of the physical system at a given moment of time corresponds to a point in this space, and the temporal evolution of the system is described by the motion of this point. A *phase space trajectory* is a curve in the phase space of a physical system that describes the evolution of the system with time (from a mathematical point of view, a phase space trajectory is a solution of Hamilton's canonical equations). For each point in the phase space, there is only one phase space trajectory passing through it. This geometric description flourished in the nineteenth and twentieth centuries, and is the theoretical foundation of contemporary classical mechanics. For more details and references, the reader could consult the modern overview (Arnold et al. 2006) and the growing body of online information provided in the *Scholarpedia*.

Symmetries and Conservation Laws

One of the most important ideas in mechanics (and in physics in general) is the connection of the symmetries of the system with the existence

of *conserved quantities* or *invariants*, that is, quantities that do not change in time (Borchert 2006). For example, from the plausible assumption that time is homogeneous (i.e., that the evolution of a physical system from certain initial conditions does not depend on the initial moment when we let the system evolve), one can derive the law of conservation of energy. These ideas were generalized in early twentieth century by Emmy Noether (1882–1935) who formulated a general mathematical theorem relating symmetries and conservation laws. Together with the modern geometric methods of mechanics (especially taking into account the symplectic geometry behind Hamilton's equations) and an area of mathematics called “group theory,” these ideas provide a method for reduction of physical systems with symmetry. The reduction procedure eliminates the redundant coordinates from the original phase space of the system and replaces the original phase space with a phase space with smaller dimension which describes the evolution of the system in the most efficient way (see Arnold et al. 2006, Chap. 3).

Theory of Dynamical Systems: A Neo-Qualitative Period of Classical Mechanics

A radically new point of view on classical mechanics was developed in the studies of Henri Poincaré (1854–1912) culminating in his 3-volume magnum opus *Les méthodes nouvelles de la mécanique céleste* (“New Methods of Celestial Mechanics”), published in the last decade of the nineteenth century. Instead of concentrating on one particular phase space trajectory, Poincaré proposed to study the behavior of all possible phase space trajectories of the physical system, that is, all possible evolutions of the system starting with all allowed initial conditions. The family of all phase space trajectories in the phase space of the system is called the *phase portrait* of the system. Within this framework, key questions of interest are “Does the system have periodic solutions?” or “Are the velocities of the particles bounded?” or “If the

system is perturbed slightly, does the behavior of its solutions differ significantly from the behavior of the solutions of the original system?” Poincaré realized the importance of such qualitative questions and understood that the answer to such questions is intimately related to the global geometric properties of the phase space of the system. These new ideas were advanced significantly in the 1920s by George Birkhoff (1884–1944).

Poincaré and Birkhoff enriched mechanics by defining new goals and by providing new tools; the area of physics and mathematics created in their works was called *theory of dynamical systems*. This theory emphasized the importance of the qualitative theory of differential equations – a field of mathematics that was virtually nonexistent before their work. Instead of solving the equations explicitly, the theory of dynamical systems is interested in the behavior of whole sets of trajectories in the phase space and in particular in their stability. In connection with this, it studies the *bifurcations* of the system, that is, the abrupt changes in the phase portrait caused by changes of the values of the parameters of the system. The qualitative features of the phase portrait of the system are closely related to the existence of certain geometric objects in the phase space, for example, *invariant manifolds*. An invariant manifold is a surface in the phase space of the system such that each phase space trajectory starting from a point on this surface stays on the same surface forever. Clearly, the presence of an invariant manifold is an obstruction to the possible qualitative behavior of the system because phase space trajectories are not allowed to cross an invariant manifold.

Another fundamental innovation in the theory of dynamical systems is that, since it studies the behavior of whole sets of phase space trajectories, it has to employ probabilistic concepts in dealing with the physical system. This makes a connection with *statistical mechanics* – an area of physics that studies the properties of systems consisting of a very large number of particles so that the particles cannot be described individually (two examples of such systems are gas in a container or a crystal). Poincaré and

Birkhoff were among the creators of a new field of physics and mathematics called *ergodic theory*, whose main object of interest is the evolution of the probabilities related to the description of the system. The probabilistic approach is also related to *information theory* which studies the quantification of information and is of great importance for modern communication systems.

Further Developments in the Theory of Dynamical Systems

Initially created by Poincaré within the framework of celestial mechanics, the theory of dynamical systems evolved quickly, often stimulated by the rapid development of science and technology in the twentieth century. For a riveting popular history of dynamical systems, see (Gleick 1987), and a scholarly analysis can be found in (Aubin and Dahan Dalmedico 2002).

In the early days of radio engineering, Balthasar van der Pol (1889–1959) noticed strange irregular noises in experiments with radio circuits, which motivated mathematical studies by Mary Cartwright (1900–1998), John Littlewood (1885–1977), and Norman Levinson (1912–1975) in the 1940s. These studies culminated in the discovery by Stephen Smale (b. 1930) in the mid-1960s of a structure that is at the heart of modern theory of dynamical systems, which is now called the *Smale horseshoe*. If a dynamical system has a Smale horseshoe, then it exhibits complicated behavior (“chaos”).

A fundamental mathematical result on the behavior of Hamiltonian dynamical systems (i.e., dynamical systems described by Hamilton’s canonical equations) is the celebrated *KAM theorem* named after Andrey Kolmogorov (1903–1987), Vladimir Arnold (1937–2010), and Jürgen Moser (1928–1999), who proved it in the 1960s. It is concerned with the persistence of certain types of motions in a completely integrable Hamiltonian system under small perturbations. The behavior of the phase space trajectories in a completely integrable Hamiltonian system is very orderly – each phase space trajectory belongs to a torus (a particular kind of

a surface) in the phase space of the system. The KAM theorem states roughly that, under suitable assumptions, most of these invariant tori survive (and are only slightly deformed) when the system is slightly perturbed; hence, the “order” in an integrable system is not destroyed completely by small perturbations, but instead the “disorder” occurs in the system gradually as the perturbation becomes stronger.

The advent of modern computing devices influenced deeply the development of modern physics. One of the first computers, MANIAC I, was used in the early 1950s by Enrico Fermi (1901–1954), John Pasta (1918–1984), and Stanislaw Ulam (1909–1984), who studied numerically a one-dimensional chain of particles linked by springs (where the springs behaved slightly nonlinearly) – a one-dimensional analogue of atoms in a crystal. The results of their numerical simulations were strikingly different from what the scientists expected, thus showing that some very foundational ideas in physics (related to ergodic theory) had to be reconsidered.

Another remarkable discovery came from meteorology in 1963, with the publication of the famous paper “Deterministic Nonperiodic Flow” of Edward Lorenz (1917–2008). Lorenz modeled on a computer the phenomena in the atmosphere when it is heated from below by the Earth surface. He used a system of three nonlinear differential equations that have the feature that, due to the dissipation in the system (i.e., the loss of energy due to the viscosity of the air), as time passes, a three-dimensional domain tends with time to a set of lower dimension called an *attractor*. From the numerical studies of the attractor in the Lorenz system, it looked like it is a set with a complicated geometric structure. The dimension of the attractor seemed to be a non-integer number; such objects were called *strange attractors* (the word “strange” is sometimes used in this context with a different meaning). The concept of objects of noninteger dimension was studied in pure mathematics since the early twentieth century, notably by Felix Hausdorff (1868–1942). The presence of an attractor in the Lorenz system of differential equations made it clear that objects of fractional dimensions are not

only a mathematical curiosity but occur naturally in physical systems. Usually, such objects coming from physics reveal *self-similarity*, that is, a portion of the object looks approximately like the whole object under appropriate magnification. The ubiquity of such object in natural phenomena was brought to mainstream mathematics and physics by Benoît Mandelbrot (1924–2010), who named them *fractals*. Today, fractals are commonplace in natural sciences and engineering, and there are many concepts of dimension that are useful in different contexts.

It turned out that the Lorenz attractor has also the property that the distance between two nearby points on the attractor grows exponentially fast with time or, in technical terms, exhibits *sensitive dependence on initial conditions*. This sensitive dependence – metaphorically called the *butterfly effect* by Lorenz – gives an idea why there are fundamental difficulties in long-term weather prediction.

The attractor observed numerically by Lorenz turned out to resist rigorous mathematical analysis, so John Guckenheimer (b. 1945) and Robert Williams (b. 1928) introduced a “geometric model” for the Lorenz equations – a system that exhibits the same features as the ones observed numerically for the Lorenz equations but is simpler and hence amenable to rigorous analysis. The existence of an attractor in such geometric models was proved rigorously, and its properties were studied extensively. However, the question whether the attractor in the original Lorenz equations indeed exists remained open. In 1997, Smale posed this question as one of the 18 “Mathematical Problems for the Next Century.” The question was answered positively the very next year by Warwick Tucker (b. 1970), who also proved rigorously that the attractor is robust, that is, it is not destroyed by small changes in the coefficients in the Lorenz system. Tucker’s proof was *computer-assisted*, that is, it used a computer for numerical computations but – unlike in the traditional way computers are used – kept track of all possible numerical errors, which made his proof mathematically rigorous. This episode provides an interesting example of the interactions of modern mathematics and computing.

Determinism in Classical Mechanics

Newton’s laws are evolution equations, that is, if one knows the masses, positions, and velocities of all objects at some moment, as well as the forces of interaction between the objects, the whole subsequent motion of the bodies is completely determined (i.e., can be calculated with arbitrary accuracy). The uniqueness of the evolution in classical mechanics is the basis of the determinism of Pierre-Simon Laplace (1749–1827). If the world is governed by the laws of classical mechanics, then Laplace’s determinism holds, and there is no free will. There are, however, some situations when the equations of classical mechanics admit nonunique solutions, for example, when the force is proportional to the square root of the velocity (see the example of Hutchinson in the article of Bishop in (Borchert 2006)). The new developments in the theory of dynamical systems – in particular, the sensitive dependence on initial conditions, the probabilistic description of the behavior of a physical system, and the connections with statistical mechanics – pose a host of new problems related to determinism.

Classical Mechanics and Experiment: Connections with Other Branches of Science

Since mechanics is a natural science, the experiment is the ultimate test for correctness of its basic principles. One of its early triumphs is the prediction of the existence and location of the planet Neptune by John Adams (1819–1892) and Urbain Le Verrier (1811–1877) from the observed irregularities in the motion of Uranus caused by Neptune. Classical mechanics is the theory behind the functioning of any mechanical device, from a bicycle to an airplane.

A recent spectacular success of the theory of classical mechanics was the rescue of a Japanese lunar mission in 1991. The spacecraft Hiten was orbiting the Earth with only about 10% of the fuel necessary for it to go to an orbit around the Moon in the “standard” way. Using the subtle

gravitational interactions between the Earth and the Moon, Edward Belbruno (b. 1951) succeeded in changing the trajectory of Hiten to send it to an orbit around the Moon, thus salvaging the mission.

Classical mechanics is the oldest area of physics, and its ideas and methods have influenced deeply all other areas of modern physics. The variational principles and the ideas of symmetries and conservation laws developed for the needs of classical mechanics but have been used extensively in all areas of modern physics and have often been the main guiding principles in deriving new equations or rethinking the old ones. The equations of mechanics of Hamilton and Hamilton-Jacobi were used in developing the theory of quantum mechanics and optics (► [Quantum Theory](#)). The principle of relativity of Galileo was one of the main ideas in theory of relativity (► [Relativity](#)).

Many developments in mathematics have been motivated by the needs of mechanics. The classical example is Newton's invention of calculus. Topology (originally named "analysis situs") is a large branch of modern mathematics that was first developed by Poincaré in his work on celestial mechanics. Modern theory of differential equations was revitalized in the twentieth century thanks to the problems posed by the theory of dynamical systems. Modern mechanics is also intimately related to geometry, group theory, and other mathematical disciplines. As mentioned above, theory of dynamical systems provides connections with statistical mechanics, ergodic theory, information theory, dimension theory, etc.

The theory of dynamical systems expanded the goals of classical mechanics in new directions. While, before, the main problem was to solve the equations governing the temporal evolution of the system for any particular choice of initial conditions, theory of dynamical systems tries to understand the mechanism responsible for the behavior of the physical system, that is, to understand *why* the system is behaving in a certain way. To this end, theory of dynamical systems often employs simple *models* that have similar behavior as a complicated system and analyzes in detail the

model – the geometric models for the Lorenz equations mentioned above are an example of this approach. Another such example is the suggestion of the biologist Robert May (b. 1936) in the mid-1970s to use simple equations to model complicated ecological phenomena since, despite their simplicity, the solutions of these equations can exhibit a complicated behavior. Around the same time, Mitchell Feigenbaum (b. 1944) studied numerically the so-called *period-doubling bifurcations* of one-dimensional functions and noticed that certain quantities are *universal*, that is, that functions can be divided into classes such that these quantities have the same value. Feigenbaum proposed an ingenious explanation of his observations that was based on *renormalization* – an idea borrowed from the arsenal of statistical physics. Namely, he interpreted his numerical results as a manifestation of some phenomena that occur in the *space of functions* – the space where the functions "live" – which is infinitely-dimensional! This suggestion spurred an unprecedented surge of activity and has been employed – with appropriate modifications – to many complicated physical phenomena, deepening our understanding of nature.

Media Studies

Jill Dierberg¹ and Lynn Schofield Clark²

¹Communication and Digital Media, Carthage College, WI, USA

²University of Denver, Denver, CO, USA

Media studies as a discipline draws upon roots in early twentieth century social theory and literary criticism. At that time, scholars in the USA and the UK were concerned with social problems arising in relation to industrialization. Scholars such as Robert E. Park, W.I. Thomas, George Herbert Mead, and Florian Znaniecki in what is known as the Chicago school of sociology questioned how well new immigrant communities were adjusting to urban life which led John Dewey to ponder whether the then new medium of newspapers would assist in securing a greater sense of community and led Herbert Blumer to oversee the first empirical studies of the impact of films on children and young adults. At the same time, literary critics in the UK, Frank R. and Queenie R. Leavis, were concerned that industrialization would destroy the cultural continuity of English language and literature. Unlike the New Critics of the USA at the time, Frank R. Leavis

was concerned that fiction and poetry could not be understood apart from their cultural contexts. This centering of culture in understanding textual artifacts became key to the work of Leavis' student Raymond Williams, who, along with Richard Hoggart and E.P. Thompson, were influential leaders in what came to be known as the **British cultural studies** tradition that is widely influential in today's field of media studies.

Media studies addresses questions related to media texts, processes of **media production**, and media audiences. This interdisciplinary field continues to draw upon social and literary theory as well as art history, aesthetics, political economy, psychology, rhetoric, and philosophy as it grapples with questions of media influence in society and in the lives of individuals. The US tradition of media studies was largely informed by **positivist** empirical inquiry until the 1970s, when the British cultural studies tradition and its Marxist orientation became more influential in conjunction with the rise of feminist thought, ethnic studies, and other critical traditions that questioned the assumptions upon which empirical research had been founded in the past. Also influential was what became known as the ► [Frankfurt School](#), as German Jewish expatriates Theodor Adorno, Herbert Marcuse, and Walter Benjamin struggled to understand the influence of media in Hitler's regime and the failure of a working class revolution in Europe. This led to a greater interest in the role of media in consolidating support for powerful regimes through the securing of what Italian social theorist Antonio Gramsci had termed ► [hegemony](#).

With developments in understandings of the social constructed nature of reality in the 1970s and the growing influence of British scholars, media studies scholars in the USA similarly began questioning the assumption that news media transparently conveyed "facts" to audiences that then unproblematically understood the news as "truth." Herbert Gans, Gaye Tuchman, and Todd Gitlin each wrote influential critiques of the US news industries, exploring the pressures and cultures of newsrooms as well as the assumptions and biases that tended to frame the reporting of the women's and student antiwar

movements. Media studies scholars then began pointing out that, whereas media systems were not intentional in creating or maintaining certain viewpoints, their drive to retain profits from the widest possible audience placed them in a societal role of maintaining certain perspectives while delegitimizing others.

These debates over the role of the media in legitimizing and delegitimizing truth claims have become of central importance in the debates about science in contemporary culture. In the past few decades, competing explanations for scientific understandings have captured media attention. This has happened as groups such as the Discovery Institute and its Center for Science and Culture have effectively inserted “intelligent design” into public discussion, which has happened as they have presented their view as a challenge, or “the other side of the story,” in contrast to evolution. Thus they have appealed to the reporting practices that aim for telling “both” sides of the story in order to illuminate truth. Once the media frame the debate as evolution versus “intelligent design,” the latter is granted legitimacy as a theory of equal standing to evolution. In this sense, the media are implicated in the rise of popular support for claims that are scientifically inaccurate yet that appeal to people on an emotional level.

Popular culture, too, plays a role in relation to scientific understandings. Rather than providing legitimacy for certain viewpoints, however, popular culture just as frequently serves to delegitimize scientific truths, essentially flattening all truth claims to stories that may or may not be true. Moreover, popular culture can provide people with symbolic resources that help them to associate with certain cultural groups and distance themselves from others. As such, fan communities and ritualistic consumption of certain media become practices that bring coherence to those with common ideological commitments, thus enabling popular culture to function in a manner similar to a religion.

Essentially, popular and news media have come to play a significant role in the search for truth that has long been a central part of both science and religion. Media such as books,

television, the Internet, and popular films provide scientists, religious scholars, and lay people access to a vast set of resources for thinking about and evaluating truth claims according to a variety of differing criteria, including emotional as well as rational responses. As media become ever more tailored to personal interests, the ways in which diverse populations evaluate and act upon truth claims stands to become even more of a challenge to advancing scientific understanding.

Media studies scholars do not take an authoritative stance with regard to particular truth claims. Rather, they are interested in sorting out how truth claims are made, what societal consequences may have resulted from the legitimizing of such claims, and how various constituents in society – including professional media practitioners as well as audiences of media – have responsibility for increasing, rather than decreasing, the potential for both improved lives and for the maintenance of a safe environment. Today, the media are the stage upon which such issues are increasingly discussed, debated, and decided, and thus media studies has become an important conversation partner in the discussions about the relationship between science and religion.

Mediatic Societies, Theology in

Alexander Darius Ornella

[Theology and media](#)

Description

“Theology *in* mediatic societies” is a rather recent field of enquiry which is interested in both today’s context in which theological thinking unfolds and how theology is done in this context. The increasing interest in this field expresses the growing awareness that theological language about God and about the relationship between God and his creation is (1) always already expressed in (linguistic) symbols and images and (2) it is always already shaped by the cultural context, that is, the culture, language,

images, and symbols of a specific time and place. The people who do theology as well as those who practice religion are part of a specific culture and share in a common symbolic understanding which transforms over time. Thus, any serious theological thinking has to consider the sociocultural, political, and economic matrix in which it finds itself. Today, this matrix is increasingly shaped by media (Deacy and Ortiz 2008, p. 3; Marsh 2007, p. 27 f; Campbell 2010, p. 2–6, 19–40).

In the past few decades, theology’s context, that is, the cultural-mediatic-religious sphere, has radically changed and transformed. Religious topics, symbols, and language have dispersed from the realm of traditional religious communities into the media sphere. Different media and media formats explicitly, implicitly, or very subtly pick up either religious topics and/or religious symbols, images, and language. In particular in the early 2000s, we could witness a rise in the number of books, TV series, films, comics in their Western forms and in their Japanese versions of manga and anime that featured religious figures, saviors, the eternal struggle of Good versus Evil, angels, demons, or religious topics such as sin, salvation, and redemption. Media can also contribute to a subversion or affirmation of (religiously informed) gender roles. Examples (that have also caused religious and theological controversies) range from print, such as esoteric, wellness, and fantasy publications, to commercials, TV series and films, various sci-fi productions, as well as web sites of Christian communities and new religious movements, podcasts, and streaming media.

The field of enquiry “theology *in* mediatic societies,” then, is interested in how these more and less subtle uses of and references to religious symbols and language in various contexts might contribute to a change in the understanding of theological concepts and terminology such as grace, salvation, incarnation, and ultimately the reconfiguration of what is understood as “religion,” religious practice, the self-understanding of humans as being created in the image of God and fundamentally oriented toward him.

Further, theology is interested in the media-user/recipient interaction ► [Popular Culture and the Mass Media, Sociology of](#), ► [Media studies](#). Today, people engage and interact with a variety of different media with different motivations and purposes in their quest for meaning. From the variety of offers available, they are able to choose whatever religious offer or offer for meaning making caters best to their individual needs. Further, as Hoover and Campbell point out, (the practice of) religion, media (practices), and practices of meaning making increasingly overlap and are often intertwined (Hoover 2006; Campbell 2010). These phenomena, in particular in Western societies, have been described with terms such as ► [religious or spiritual marketplace](#), religious seeking, or the ► [commodification of religion](#) (Roof 1993, 1999, pp. 8, 69, 77). Media play a fundamental role in these phenomena because they are the sites where elements of meaning are offered and discussed. Thus, theology is interested not only in the religious narratives and elements to build a religious identity from media offer, but how people interact with media and for what purposes, what media do with the people, and what notions of a “good life” and ideas of the human being are generated in this interrelated process.

Methodologically, there are several approaches to understand and frame the relationship between theology *and* its mediatic (and cultural) context. Each approach is shaped in part by the question of how and why theology should engage with and study media, by what seems to become an increasing gap between a liberal, conservative, and fundamentalist understanding of how theology and media (or popular culture) should interact, as well as the theological tradition, for example, Anglican, Catholic, Lutheran, Methodist, Orthodox, etc. One way to systematize the different approaches to the relationship between theology and its context is based on Richard Niebuhr’s classification presented in *Christ and Culture* (1951): (1) Christ against culture, (2) Christ of culture, (3) Christ above culture, (4) Christ and culture in paradox, and (5) Christ the transformer of culture. Lynch points out that this approach, while valuable, has some

limitations, for example, how a discourse between theology and popular culture might look like, and suggests the following differentiation: (1) the applicationist method, maintaining that core theological values should critically be applied to analyze tendencies and transformations in media culture; (2) the correlational method which is influenced by Tillich’s work and maintains that theology should offer answers to questions raised in a mediatic society or in popular culture; (3) the revised correlational method which understands theology and mediatic/popular culture to be in a mutual relationship in which both can inform and enrich each other; (4) the praxis model which he relates with liberation theology, that is, this approach is similar to the revised correlational method but focuses on how both theology and mediatic/popular culture can contribute to human liberation, freedom, and equality (Lynch 2005, pp. 101–105). While there is sometimes a tendency to try to associate each of these approaches with a particular denomination, it is important to point out that the lines for a denominational classification are increasingly blurry. One widely accepted approach, for example, is to understand the cultural matrix, including arts, theater, film, traditional, and new media, as a place where the (religious) subject can encounter the o/Other. This is not to instrumentalize the cultural matrix for religious or theological purposes, but rather it is an expression of the awareness that this matrix is an autonomous – yet theologically highly relevant – place where meaning is constructed and that offers a critical reflection on theological and sociocultural developments (Larcher 2005).

There are several disciplines that deal with aspects of today’s context of theology, for example, theology and literature, theology and film, theology and the arts. What is important in all these fields is that art, media, or media contents do not need to be explicitly religious (or Christian) to be theologically relevant, rather they can be understood as part of a broader aesthetic (or religious) undercurrent present in today’s society (Larcher 2005).

Finally, talking about religion/theology and media, one needs to be aware that the understanding and experience of “religion” is changing. That includes not only the media culture as the context of and for theology, but the ways and the contexts in which people encounter “religion” or “the religious”, or the way we/academics talk about and conceptualize “religion”. In *Film as Religion*, John Lyden (2003) analyzes the “religious functions” films can have and perform today. Enzo Pace (2011) argues that religion is a communication system that deals with ultimate meanings. Theology is a contextual discipline; incorporating or considering these different approaches to religion can therefore be a fruitful contribution to theological discourse.

Self-identification

Science

The question, if theology qualifies as “science” poses a terminological problem. Particularly in English, “science” usually means natural sciences. In German, for example, the term “Wissenschaft” is much broader denoting any academic discipline, including humanities, philosophy, and theology. Often, the term “<exakte> (exact) Wissenschaft” is used to refer to natural sciences. Thus, theology does not self-identity as “science” if the term is understood as natural sciences.

There has been a long-standing discussion within theology if, why, and under what circumstances it should self-identify as *Wissenschaft* or academic discipline considering (1) the transcendental “object” of reflection of theology, that is, the mystery of Christ, (2) its relation to a specific religious community or church, their religious practices and faith traditions, and (3) its relation to other academic disciplines and the technosciences. The general consensus, however, is to identify theology as academic discipline (or *Wissenschaft*).

The term “theology” is rooted in Greek philosophy and refers to a speaking about gods/God that is philosophically and critically reflected. In a Christian understanding, the

critical, responsible, and rational reflection on faith is not a surplus, but one of its fundamental characteristics. Throughout the history of Christian thinking, several theologians have expressed and supported this notion, for example, Anselm of Canterbury with his understanding of *fides quaerens intellectum* (“faith seeks understanding”). More recently, Pannenberg pointed out that theology can only be adequately understood as “Wissenschaft von Gott” (“science” or academic thinking about God) with God as ultimate reality as its object of reflection (Pannenberg 1977, p. 299). As such, it is concerned with an epistemological and philosophical discourse on the possibilities of knowledge (Honnefelder 1989), and the development of theories to describe the various aspects of the reality of human existence. The several theological disciplines do not share one single “theological” method, but different disciplines draw on different methodologies.

The field “theology in mediatic societies” is not a distinct discipline, rather it is an approach or field of enquiry within several theological disciplines (e.g., ► [Practical Theology](#), ► [Systematic Theology](#)) that study theology in today’s context. Particularly in the late twentieth century, several disciplines have emerged that explicitly deal with the media context from a variety of perspectives, for example, theology and film, theology and literature, theology and arts. They use a variety of methods and approaches, for example, hermeneutics (cf. Also ► [Hermeneutics, Theological](#)), close reading, reception theory, empirical social research, as well as other methods from literary, linguistic, cultural, film, media and communication studies, sociology, and religious studies. In particular, these fields are interested in formal and technical aspects, that is, the characteristics of a medium, how media content is made and staged, the processes of media power, and how the audience engages with media and tries to make sense of what is presented to them.

Religion

Theology understands itself as rational (and academic) speech of God that is guided by the

mandate of 1 Peter 3:15: “But sanctify the Lord in your hearts: and be ready always to give an answer to every man that asketh you a reason of the hope that is in you with meekness and fear.” “Reason” is to be understood not just as a confession of faith but as critical reflection of faith. Thus, theology itself is not a religion but is rooted in a religious tradition and reflects on the tradition it is rooted in and its religious practices; it is a rational reflection on faith and faith practices in their specific contexts. Today, the context in which faith is practiced, religion is lived and experienced, and religious content and symbols are encountered, is shaped by media; often, the religious is encountered *in* media.

Characteristics

The field “theology *in* mediatic societies” with its related disciplines is a rather recent field of interest. It is interdisciplinary in nature because it deals with sociocultural, media, and technological phenomena, is interested in a critical dialogue between its own tradition and present day’s media culture, and utilizes methods from a variety of academic fields, including the empirical sciences. Several theological disciplines have their own interest and motivation to venture into the media realm, for example, pastoral theology in its reflections on how media can contribute to pastoral care, or on a more fundamental level: how media change the ways pastoral care can and should be done or what the omnipresence of media and religious symbols in media means for the life of a religious community; the role of media in education in general and in religious pedagogy (*Religionspädagogik*) in particular; in liturgical studies if and how media practices, media rituals, and religious rituals portrayed and described in media change religious practices. The study of the mediatic context is important for ► [fundamental theology](#) (*Fundamentaltheologie*) as well as it understands itself as conducting basic research located at the points of intersection between theological tradition and sociocultural practices such as arts and media.

The challenge for thinking and doing theology in today’s mediatic context is – as Marsh points out with his differentiation between “theology of/from/through culture” – not to deduce theological insights from media presentations or evaluate media culture based on theological truths or dogmas but be aware of how religion and culture interact and to engage in a “critical dialog between film (or media culture) and Christian tradition” (Marsh 2007, p. 166 f.).

Relevance to Science and Religion

Theology (in particular Catholic theology) has had a long-standing but ambiguous relation toward the sciences. On the one hand it supported and encouraged scientific discovery, on the other hand it has often perceived scientific findings as conflicting with theological ideas. Often, the validity of scientific findings has been judged according to theological ideas or theological insights have been based on or referred to scientific findings.

The field of enquiry “theology *in* mediatic societies” is interested in the area of “Science and Religion” because media have become the place where scientific insights are presented, meaning is constructed, and fundamental questions of human existence are discussed. In particular, this concerns the vast amount of popular science publications. This, however, is problematic. Often, theological reflections (particularly in areas that seem to touch on theological questions, e.g., biology, physics) draw and rely on popular science. This is problematic because popular science itself is an ambivalent enterprise where the lines between scientific facts and hypotheses, speculation, and thoughts on ontology are blurring. Theology would do well to critically analyze speculative, ontological, and metaphysical endeavors by scientists, but not to rely on them for theological thinking as this – ultimately – would result in “bad” theology (Mutschler 2005, p. 224 f.).

Representations of the technosciences and their achievements or of the technoscientific future of humanity in literature, film, or TV

series, for example, *Battlestar Galactica* (2004–2009), have often been influenced by religious and theological thoughts or express religious and theological ideas. These representations, in turn, become a pool of symbols for popular sciences to draw on and connect scientific endeavors with topics such as human longing and aspirations, venturing beyond frontiers, and hopes and visions of what the human future might or should look like (Graham 2002).

Further, popular science publications and publications on artificial intelligence and robotics often feature strong religious language and terminology. Such publications often deal with the question of the meaning of the cosmos and of human life, they often blur the lines between findings in the natural sciences and the God question, or attach a notion of (paradisiacal) longing to technological developments. Another reason why popular science publications often resort to religious symbols and language is to back up their own authority (Geraci 2007).

With regard to the relation between science, religion, and theology these phenomena concern, for example, the atheism debate and its presence in media as well debates and publications on evolution, creationism, intelligent design, artificial intelligence, and robotics. The debates on atheism or evolution versus creationism are often publicly staged, that is, staged in and through various media and media formats. These phenomena can be witnessed in particular in the USA, but in the late twentieth and early twenty-first century, European voices from the political, religious, and theological sphere have fueled the debate. Examples are Richard Dawkins' (2006) bestseller *The God Delusion* or the 2008/09 "There is probably no God" ad campaign in the UK, Germany, and several other countries (the campaign is not related to Dawkins but draws on some of his arguments).

Sources of Authority

There are two relevant sources for this field: (a) the *symbolum*, the declaration of faith, and

the tradition the respective theology is rooted in and its (critically reflected) faith practices (cf. ► [Constructive Theology](#), ► [Fundamental Theology](#), ► [Systematic Theology](#)); (b) any media (e.g., literature, film, web sites), media content, and media arts that express an authentic longing, are open to discourse, meaning making, and the o/Other, and deal with fundamental questions of human existence. As such, media, their content, and how they are used reflect tendencies and developments in society, and express what a society or different generations are longing for. Media, such as film, also discuss theologically relevant and existential questions, for example, the meaning of life and death, and are involved in the various processes of (religious) identity formation.

Explicitly religious media or media content form just a small fraction of source material theology considers to be relevant when getting involved with its media context. More importantly – and often more fruitful – are profane or secular media, media content, and media art because they express contemporary experiences and deal with questions contemporary society is interested in and dealing with. This complex process is shaped by different interests and subjects and is further complicated by the reception process; why and how something is meaningful for one individual might not be relevant for another. Seen from this perspective, a whole range of nonreligious media material can be theologically relevant.

Ethical Principles

As with every academic discipline, researchers are expected to disclose the methods and sources used, cf. also the entries on ► [systematic theology](#), ► [practical theology](#), and ► [fundamental theology](#). Further, impartiality toward various media and media content, their ability to provoke the question of the o/Other, as well as respect toward the different processes of (religious) meaning making at work in the media-user interaction are required.

Key Values

The “thorn of alterity” and the encounter with the o/Other can be experienced in various mediatic and artistic settings addressing the whole human being making it necessary for theology to pay attention to a reception process that involves all human senses (Knauss 2008). Thus, any research in this area has to be guided by the basic assumption that today media are a fundamental part of human experience. Further, an openness and curiosity for the different phenomena at work, for modern (and authentic) media experiences, the complex and rich religious traditions, and new religious and spiritual experiences is vital. It is also important to be aware of and take seriously the tension between the respective religious tradition and media culture any theology finds itself in, to be open to self-criticism and to be open to be challenged by this encounter by media culture.

Theological engagement with media culture is not to be understood as one-way enterprise, that is, either draw on media as the sole source for theological reflection disregarding the respective faith tradition or impose theology’s views on media and their content. Rather, this engagement has to be understood as a two-way dialogue where both participants can inform and learn from each other. Robert Johnston summarizes the attitude with which theology should encounter media: “Personal evaluation, including theological dialogue, has its place as in any human encounter, but it must follow the act of first looking and listening” (Johnston 2006, p. 239).

Conceptualization

A – short – definition of the following terms is problematic because there is not one theology but a rich diversity of theological traditions, for example, Catholic, Lutheran, Anglican, and Orthodox. Each tradition would have a slightly different interest in these terms and there are often different approaches to understand a term and its impacts within a tradition.

Also, the theological understandings of most of these terms have had a long history, starting with Greek philosophy, their conceptualization in the Bible, and in discourse with philosophy. And neither is there agreement in the natural sciences about how to define these terms. Any attempt to define or conceptualize these terms would have to consider their conceptual history which would go beyond the scope of this entry. Therefore, all that is offered here is a very brief – and thus insufficient – sketch.

Nature/World

“Nature” can have several meanings. Nature can refer to creation and express the religious and theological understanding of the goodness of nature and creation. Nature can also refer to human nature and that what ultimately and indubitable characterizes being human and human existence, for example, the burning question of meaning of life, the relatedness with and orientation of human existence toward God (cf. ► [Constructive Theology](#)). Nature is also often understood in its relation with (or difference to) culture and/or the artificial, that is, what is produced by human intervention. Today, what is understood as nature or perceived as the world we live in (and ultimately the understanding of our own nature) is shaped by our encounters and interactions with media and media images and representations of nature.

Virtual worlds pose the question of their status and their relation to the “actual” or “real” world. There are several approaches to this question. One would understand the virtual world as fundamentally and ontologically different, another – and increasingly common – one understands the virtual world as part of the world we live in, where communication and meaning making happens.

Human Being

Theology understands the human being as being created in the image of God and as his representative and steward within creation. Humanity’s relatedness with God is not a surplus or choice but fundamental to the human being and his/her

existence. There is, however, a diversity in understandings of the implications of “the human nature” and developments in the late twentieth century in theology, for example, feminist theology *queer theology*, liberation theology (cf. the entries on ► [Theology of Liberation](#)), are calling for a reevaluation of several aspects of human existence, for example, the question of gender.

Contemporary approaches (e.g., Dirscherl 2006; Schobert 2006) have emphasized the contextual nature of humanity. Being human always, already means being in time and in space; thus, any definition or idea of the human being has to be understood as an expression in and of time, that is, the question of what it means to be human is always explored in a specific time and context, making a permanent theological reevaluation necessary. A theological anthropology that considers – or is based on – the mediatic and technological context as being fundamental to human self-understanding would be vital but only exists in rudimentary forms and has to be further developed. Such a reevaluation has to consider that ideas about human existence and the meaning of life are nowadays (re)negotiated in a media setting, often outside of traditional faith communities, and often drawing on a variety of religious building blocks.

Life and Death

Theology understands all life as God’s gift, that is, God is the source of all life – human and nonhuman alike. “Death” can have several meanings; with regard to human life, it refers to the end of earthly life, expresses its uniqueness, and a passageway to the life after death which is, however, qualitatively different from earthly life (cf. ► [Systematic Theology](#)).

A challenge for a theological concept of life (and death) will be any form of virtual existence or artificial intelligence, since this would not only raise questions about how life itself is understood, but personhood, the relation between mind, materiality, and soul, and if and how human life is distinct from any forms of artificial lives that might emerge.

Reality

Theology is speaking and reflecting about an ultimate reality. Everything that exists has its roots in this ultimate reality and is oriented toward it. In the monotheistic theologies, this ultimate reality has traditionally been referred to as YHWH, Allah, or God. The theological understanding of “reality” then is shaped by (1) the biblical understanding of reality which itself has changed over time and (2) the understanding of God as the ultimate reality, (3) creation as the reality that is given to us. God, however, is not only the ultimate reality, he is the reality *of* and *for* his people.

With developments in the media sphere, for example, the rapid spread of communication media and embedded computing and the emergence of virtual realities, what people understand their reality to be depends on, among others, people’s experiences, media representations of the world, and how people interact with the world and with others through media. Lived reality and religious experiences and realities are thus not separate realms but overlap in and through media. Similar to aesthetic experiences, theology understands religious experiences to refer to and to be rooted in something real, something that consists of both an objective part, that is, that which causes a religious experience, and a subjective part, that is, the religious meaning the subject constructs in this engagement.

With regard to “science and religion,” theology holds that sciences with their methods have only partial access to reality, that is, the part that is currently – or will be – available to scientific, empirical, physical, and mathematical methods. Theology, on the other hand, deals with God as the ultimate and all-encompassing reality.

Knowledge

The common definition of knowledge in philosophy and philosophical theology is usually knowledge as true persuasion, conviction, or belief. It is disputed however, if it also is justified conviction (Müller 2008, p. 22). The theological understanding of “knowledge” is rooted in Greek philosophy and has developed in philosophical-theological discourse up until today. While

“knowledge,” “faith,” and “believe” have a range of meanings, theology generally opposes a contradiction between knowledge (understood as true conviction) and faith but sees them to be related. To believe is a deliberate act of faith, but faith is always also reasonable faith. In particular, theology rejects any contradiction of knowledge (in the sense of scientific facts or hypotheses) and reasonable faith. A challenge for a philosophical-theological understanding of knowledge, however, are approaches in biotechnology that want to reduce the human being to his/her mere genes.

Today, media form a valuable (but often ambivalent) source of knowledge. Therefore, theology has to analyze what is understood as meaningful knowledge, how (and by whom) meaningful knowledge is generated and how it is used.

Truth

In Christian theology, God is understood to be truth in its fullest sense. Truth, or the truth of faith, is not understood as empirically measurable, but as truth that refers to an ultimate truth or reality. In this way, the truth of faith is different, though not completely separate, from historical truth because theology holds that truth (i.e., truth as referring to an ultimate reality) cannot contradict truth (i.e., what is generally understood or experienced as truth). The theological interpretation of “truth” is shaped by the Bible (both the First and Second Testament), which generally understands God’s word to be truth and thus authentic, reliable, and trustworthy.

In a media context, it is often difficult to validate what is portrayed as being true. Media and media art, however, can open or provide a space in which the encounter with God as the ultimate truth can happen.

Perception

Perception generally refers to being aware of or becoming aware of the world. In a theological context, perception is often understood as becoming aware or being aware of traces of God in different context, for example, in explicitly religious settings or in art and media. With regard

to the engagement of theology with media it is important to point out that perception, that is, media perception and media interaction, is a complex and multilayered process that is not only a cognitive process but one that involves all human senses (Knauss 2008; cf. ► [Fundamental Theology](#), ► [Constructive Theology](#)).

Time

Time and the experience of time are fundamental to human life. Thus, being human always means being *in* time. Time is not eternal but a fundamental feature of creation. God’s *Selbstmitteilung* (self-revelation, self-communication, and self-sharing) is not understood as something abstract, but as something concrete that happens in time; he experienced time himself through the incarnation of the *logos* at a specific time and space in history. Time is structured through the history of salvation, that is, the history of God with his people and God’s work of salvation in creation. As such, time, and thus human existence and all of creation, are shaped by the eschatological tension and hope of “already” and “not yet.”

In today’s mediatic society, the fundamental experience of time as well as the relation between time and space are fundamentally transformed. Thomas points out that while in former times religion used to structure days and years, today media have taken on this structuring role (Thomas 1998). Further, media change the understanding of contemporaneity, the relation of time and space, of past, and future.

Consciousness

The term “consciousness” refers to a variety of phenomena which have already been discussed in Greek philosophy. Generally, consciousness is understood to be the foundation of *Erkenntnis* (knowledge/cognition) and includes self-awareness; cf. ► [fundamental theology](#), ► [constructive theology](#), ► [systematic theology](#). Today, theology is interested in the discourse on consciousness in philosophy as well as in the context of the mind-body/matter discussion, for example, in neurobiology (cf. ► [Neuroscience](#)).

Of particular importance is the relation between media, self-awareness, and the understanding of the self. Self-awareness includes a sense of one's place in time and space, that is, the context the self unfolds into. Today, media have become a primary source for what we know about the socio-cultural contexts and networks we perceive as our time and our space. Further, theology is interested in how media interact with, are part of, and shape different forms of consciousness, for example, personal/individual, religious, social, national, or public consciousness.

Rationality/Reason

For theology (in particular for Catholic theology), there is no conflict between faith and reason, on the contrary it emphasizes the rationality of faith. The relation between faith and reason is twofold. On the one hand, for faith it is not enough to believe but it seeks reasons for its beliefs. Reason, on the other hand, does not necessarily lead to faith (because faith is always a deliberate act) but expresses an openness toward the o/Other in its longing to question, understand, and explore; cf. ► [fundamental theology](#), ► [constructive theology](#).

Mystery

In theology, "mystery" refers first and foremost to the fullness and inexhaustibility of the reality of God's existence. This does not mean that human beings cannot know God or his existence; rather, the mystery of God includes his relation to his creation and to all human beings. Thus, the mystery of God refers to God as ultimate reality as well as God's self-revelation and self-communication in and through history and ultimately in the incarnation of the *logos*.

Relevant Themes

Media have played an important role in the development of human culture ever since (e.g., the invention of script or of printing). Today, media are accessible and available for a majority of

(at least the western) population and have thus become a fundamental aspect of everyday life (it is important to point out that there still exists a digital divide not only between the west and other parts of the earth but also within the west). Media do not only facilitate communication, but change the way we do things, the way we communicate with each other and with our environment. This raises the question of how human self-understanding will change over time. Thus, it would be vital for theology to develop a theological media anthropology that considers the variety of concepts of what it means to be human that are present in today's media society, that is, the human being as networked being. Technosciences contribute to and inform these concepts that are then portrayed and discussed in media.

Further, communication is a central aspect of human agency because theology understands the human being always already as addressee of God's "yes" to creation and to each individual human being. As addressees of God's word, humans find themselves always already in a communicative relationship with God. Human existence cannot be thought without this relationship but it is up to the individual to decide whether or not to respond to God's "yes." A challenge for a theological media anthropology, then, is the question how being human in its fullest sense, that is, as lived communication with God, can be thought if the everyday experience of communication radically changes.

Description

Medical genetics is a discipline of human medicine which is specialized in the research, diagnosis, and management of congenital disorders. As such, medical genetics is part of human genetics. However, whereas human genetics studies and describes the inheritance in man in general, medical genetics is devoted to inherited human diseases. This implies peculiarities of the genetic information, the DNA, and the genetic text itself, as well as of epigenetic factors, which influence the effect of the genetic information on an individual. In addition, congenital disorders are not limited to inherited genetic peculiarities but may also be caused by exogenous factors such as infectious or toxic agents, which may exert an adverse effect on the child during embryonic or fetal development. Therefore, acquired congenital disorders are also in the focus of medical genetics. The term “genetic medicine” summarizes subspecialties of medical genetics, which aim at genetically based treatment and prevention strategies such as gene therapy, personalized medicine, and predictive genetic testing. Medical genetics is a classical interdisciplinary specialty and reaches far into every other medical specialty.

Throughout Europe, in medical institutions the terms “medical genetics,” “clinical genetics,” and “human genetics” are being used synonymously. Medical genetics was first a subspecialty mainly of pediatricians and

gynecologists, but became a discipline of its own in the second half of the twentieth century. Departments of Medical Genetics were established in the university hospitals, and medical genetics or human genetics practices were founded subsequently.

Self-identification

Science

Medical genetics is deeply anchored in the biology of man and the natural sciences. It is based on the biochemical and biological processes of reproduction and evolution. The British biologist William Bateson (1861–1926) coined the term “genetics” to denote studies of heredity and variation. He rediscovered the work of Gregor Mendel (1822–1884), who described the principles of inheritance which are nowadays known as Mendel’s laws of inheritance. The translation of genetics into medical genetics is strongly connected with Archibald Edward Garrod (1857–1936), who in 1902 initiated his studies of inborn errors of metabolism. These errors were mainly associated with certain constellations of symptoms so that medical geneticists started to study biochemical and physical phenotypes systematically and to develop hypotheses about their origin. The chromosome theory of heredity was first formulated by Walter Sutton (1877–1916) and Theodor Boveri (1862–1915). In medical genetics, their theory was confirmed in 1959, when Jérôme Lejeune, a pediatrician and geneticist, identified the gain of an extra chromosome in a patient with Down’s syndrome. The following cytogenetic era showed that distinct chromosome aberrations result in specific syndromal diseases. Chromosome investigations were introduced in the prenatal diagnosis of the genetic status of the fetus. The clarification of the structure of the DNA by Watson and Crick in 1953, the unraveling of the genetic code by Marshall Nirenberg and H. Gobind Khorana in 1966 together with the development of DNA sequencing by Fred Sanger in 1977 initiated the molecular genetic era of medical genetics. Chromosomal rearrangements were analyzed with respect to the

involved genes which led to the identification of the gene defects of classical inherited genetic disorders such as muscular dystrophy or retinoblastoma. The gene, which causes cystic fibrosis, was the first that was identified by using molecular genetic methods only in 1989 by Francis Collins and Lap-Chee Tsui. Molecular genetic methods enabled the detection of gene defects in so far healthy individuals so that the risk of the occurrence of the respective genetic disease could be predicted more precisely. The human genome project ended up with a complete DNA sequence after 13 years research in 2003. A high grade of variation between individual genomes was found, which is responsible for the individuality of the phenotype of an individual (Quinlan and Hall 2012). Recently developed DNA-sequencing techniques made the entire genome of an individual available within 1 day. This opened a new window for medical genetics in that the genome of each individual becomes available to estimate the personal risk for inherited diseases for itself and its offspring before any symptoms may appear.

In 1960, when Peter C. Nowell and David Hungerford detected a minute chromosome, the Philadelphia chromosome, in the bone marrow cells of a patient with chronic myeloid leukemia, they confirmed the genetic theory of the chromosomal basis of cancer, which had been formulated by Theodor Boveri already. The tumor cytogenetic era revealed that chromosomal abnormalities are present in almost all tumors and paved the way to the molecular genetic studies in cancers. Nowadays, it is widely accepted that cancer on cellular level is a genetic disease. The clarification of the genetic disease mechanisms in cancer has led to the development of drugs directed to the correction of the genetic defect (Tran et al. 2012).

Religion

Religion is a framework to direct our thinking and acting according to a superordinate concept and depends on our idea of man. Human genetics and medical genetics have much influenced the idea of man, as it became evident, that inherited factors contribute to our

phenotypical appearance as well as to our physical and intellectual abilities to a very high extent. At the beginning of the twentieth century, when the first mosaic stones of the genetic basis of evolution were found, the findings were catastrophically misinterpreted, and tremendously false conclusions were drawn with respect to a superordinate concept of evolution of the survival of the fittest which led to the concept of eugenics and the horror of the Holocaust. With further development of genetics, it became evident that propagation of variation is the most important principle of evolution because selection cannot take place without variation (Perlman 2011). Medical genetics does not self-identify as a religion but is aware that the nearness to the biochemical source of life and the major source of variation, the genome, puts a particular responsibility in how to communicate genetic findings to the public in order to prevent from misinterpretation and misuse for the development of inappropriate superordinate concepts.

Characteristics

Medical genetics is distinctive among other specialties of medicine because the genome is shared by relatives of the patient. The diagnosis of an inherited disease in an individual, therefore, may have an adverse effect on healthy family members by stigmatization which may have consequences on the social and professional life. Moreover, gene defects may show pleiotropic effects as well as variable penetrance and expressivity so that the typical pattern of a respective genetic disease may only be visible if one looks at the entire family. Relatives of the patient may have minor symptoms and, therefore, need to be investigated to make the diagnosis in some cases.

Relevance to Science and Religion

Medical genetics influenced our understanding of how life comes into being and takes its course. It changed our view on normality and disease, and taught us that variety and differentness are the

primary principles of our world. Thus, the development of different religions is within the scope of this evolutionary concept.

Sources of Authority

In medical genetics, the authorities used to be scientifically interested and passionate physicians. Victor A. McKusick (1921–2008) was one of the cofounders of medical genetics as a self-contained medical specialty. He founded the Department of Medical Genetics at the Johns Hopkins University in Baltimore in 1957. In 1960, Charles R. Scriver edited his textbook “The Metabolic Basis of Inherited Disease” which was continued as “The Online Metabolic and Molecular Bases of Inherited Diseases.” Arno Motulsky (1923–) introduced the field of pharmacogenetics in medical genetics, i.e., the role of genetic variation in response to drugs. Friedrich Vogel (1925–2006) was a close friend of Arno Motulsky. He reestablished medical genetics in Germany and contributed considerably to the rehabilitation of the specialty human genetics after the Nazi terrorism. Vogel and Motulsky in 1979 published the textbook “Human Genetics – Problems and Approaches.” Alan E.H. Emery, David L. Rimoïn, J. Michael Connor, Reed E. Peyritz, and Bruce R. Korf in 1983 published the most important and comprehensive textbook in the field – “Principles and Practice of Medical Genetics.”

The need to correlate the abundance of phenotypes with the growing amount of genetic data in research and clinical settings met luckily with the development of the computer and the Internet. In 1966, Victor McKusick published the first edition of the book “Mendelian Inheritance in Man,” in which he systematically collected the symptoms and genetic basis of inherited diseases and which now is publically available as “Online Mendelian Inheritance in Man.” Albert Schinzel (1944–) in 1983 started to collect the phenotypes of patients with chromosome aberrations in his book “Catalogue of Unbalanced Chromosome Aberrations in Man”, which has now been

included in the online database ECARUCA. Felix Mitelman (1944–) in 1983 started a collection of the chromosome defects in cancer in the “Catalog of Chromosome Aberrations in Cancer” which was continued in the online database “Mitelman Catalog of Chromosome Aberrations and Gene Fusions in Cancer.” In 1991, P.L. Pearson started the human genome database within the human genome project. The entire human genome sequence is available online and linked to the major databases containing genome-related information (Fujita et al. 2011). The connection of these scientific resources provides the basis for the disentanglement of the effects of the genetic variation on the physical as well as mental health and disease of an individual.

Ethical Principles

As for every medical subdiscipline, medical genetics is guided by the oath and law of the ancient Greek physician *Hippocrates* (born 460 B.C.) who is considered the so-called father of medicine. This “*Hippocratic Oath*” has been supplemented by the rules of the *Declaration of Helsinki* of 1971.

Key Values

The key value of medical genetics is alleviating human *sufferings*, which arise from inherited peculiarities and genetic disadvantages. This includes patients with inherited diseases as well as individuals who themselves or whose offspring are at increased risk for a genetic disease.

Conceptualization

Nature/World

Nature is conceptualized as the basic environment on our globe which provides the chemical and physical prerequisites for life. World is defined as the space where nature exists.

Human Being

The human being is considered as a biological being which evolved in the struggle with the animated and unanimated environment. Upright walking and the use of the thumb as an opponent of the second finger are considered the most important evolutionary advantages and prerequisites for the development of the brain, which enabled the development of unique functions including speech, abstract thinking, creativity, and the development of ethical categories such as morality and religion (Babbitt et al. 2011).

Life and Death

Life is conceptualized as the presence of physical functions in biological systems ranging from bacteria over plants and animals to humans. In the human body, it includes functioning of the different organelles, including the *reproductive system and the genome*. Death is considered the cessation of such physical functions and important part of evolution.

Reality

Reality is considered the physical world around us that humans can observe with their senses.

Knowledge

Knowledge is understood to have an *objective* dimension, such that it is the *wisdom* that can be transferred in a verbal form from one person to the next, or has been written down in books or libraries. However, knowledge is also understood to have a *subjective* dimension, which is taken to be the amount of information a person can retrieve from *memory* voluntarily, or by being *cued*.

Truth

Truth is conceptualized as the supreme reality underlying facts and rules. Accordingly, truth is assumed to be absolute or universal which humans can grasp only partially.

Perception

Perception is the *conscious sensation* of the forces and influences the external physical

world exerts on living beings. Genetic peculiarities may influence the type and character of the perceptions due to inherited variations in the perception systems, for instance, color blindness or lack of bitter taste.

Time

Time is the fundamental category of ongoing change in the world. Humans can measure time *objectively* and perceive it owing to the changes observed in the surrounding environment. Circadian rhythms of human beings are genetically influenced so that time perceptions may vary between individuals.

Consciousness

Consciousness is the responsiveness of subjects to any physical stimulus in the outside world. It can be graded in different levels of *alertness* ranging from drowsiness to full *alertness*, which comprises crystal clear orientation concerning location, time, situation, personal biography, and full mental capability. Diseases can impair consciousness globally or in differentiated fashions.

Rationality/Reason

Rationality is a function of logical connections of empirical data which have been collected by the individual itself or been communicated from others. The interpretation of the connection of the data leads to conclusions which are expressed as reasons. Genetic factors may influence the process of the development of rationality on different levels and to different extent.

Mystery

Mystery relates to observations and experiences which may not or cannot be explained by objective criteria, cannot be influenced by us, and have a scaring character. Because we all have to rely on our genome as it is, and do not know exactly, in how far our fate is determined by it, the genome, i.e., in medical genetics, may have a mysterious character for those individuals who are susceptible to mysterious thinking.

Relevant Themes

The genome provides the connection between the unanimated and animated environment by providing the blueprint of our body. Therefore, our thinking and especially the development of religion depends on the structures which are provided by our genome. Thinking and the abstract world including religion, however, is formed by the communication with each other. The abstract world has developed since the beginning of mankind and is being stored in spoken and written language. During this time, the language has evolved like the genome, and it is evolving further (Cavalli-Sforza 2000). Thus, religion will also be evolving further.

► History of Medicine

Medical Microbiology

Li Yang Hsu

Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Related Terms

[Clinical microbiology](#)

Description

Medical microbiology, also known as clinical microbiology, is a subdiscipline of microbiology dealing with the study of microorganisms (parasites, fungi, bacteria, viruses, and prions) capable of infecting and causing diseases in humans (Baron et al. 2007; Isenberg 2003). As with other specialties in medicine, the evolution of medical microbiology is essentially a response to clinical needs. At its core is the study of the pathogenesis and epidemiology of these microorganisms, and its practical applications lie in the form of diagnostic and therapeutic guidance – intrinsically a supportive role in clinical practice (Baron et al. 2007). Today, virtually all tertiary hospitals worldwide will have an in-house microbiology laboratory to provide diagnostic services for infectious diseases (Isenberg 2003). Advances in interconnected disciplines such as immunology, genetics, and bioinformatics have led to the further expansion of this field, resulting in the development of vaccines as well as advanced genetic- and protein-based diagnostics (Isenberg 2003).

Self-Identification

Medical microbiology is a natural science derived from the development of the germ theory of disease. Germ theory challenged the ancient view that disease was spontaneously generated with the understanding that many diseases are caused by microbes that can reproduce. The scientific work of Louis Pasteur and Robert Koch in the nineteenth century was critical in advancing germ theory, and consequentially, medical microbiology and ► [Koch's postulates](#) are still currently rigorously applied to determine if a microbe causes a new disease (Winslow 1950).

Since the inception of medical microbiology, practitioners have recognized its tremendous significance in medicine and used scientific methods to expand knowledge in this field, including further understanding of how microbes cause disease and cataloging of different disease conditions caused by microbes (Isenberg 2003). The application of breakthroughs in other fields such as microscopy, genetics, chemistry, and epidemiology has resulted in a corresponding increase in the breadth and depth of scientific knowledge in medical microbiology. This has translated into both an increase in the number of subspecialties (such as medical virology, medical bacteriology, molecular epidemiology, etc.), as well as an increase in the number and complexity of practical applications in modern medicine (vaccines, microbial diagnostics, susceptibility testing, therapeutics design, etc.) (Baron et al. 2007; Isenberg 2003).

Characteristics

Medical microbiology is distinctive among other specialties in medicine in that it is virtually the only field where there is comparatively negligible emphasis on the scientific study of the human body and its processes, but yet its main focus – the study of microorganisms of medical importance – has resulted in advances in the treatment and prevention of diseases in humans (Baron et al. 2007; Isenberg 2003).

One of its most ubiquitous practical applications – susceptibility testing of microorganisms – is based on the principle that the behavior of microbes in vitro (i.e., in the laboratory on culture media) mirrors that of microbes in vivo (i.e., in the human body) where it pertains to their vulnerability to different drugs. Thus microbes that are inhibited or killed by an antibiotic in vitro will similarly be affected in vivo if the antibiotic was instilled into the diseased human at equivalent or higher concentrations. This application of medical microbiology has guided the use of antimicrobials in the treatment of infectious diseases since their development in the 1940s (Isenberg 2003). In contrast to other specialties in medicine, one unique and key driver for advances in medical microbiology is the propensity for the microorganisms to evolve. Thus microbes become resistant over time to the antimicrobial agents used to treat them, and there is a corresponding pressure to be able to quickly identify the resistance and susceptibility profiles of these microbes such that the correct drugs may be used against them.

Because of the understanding of the human host-microbe interface for disease development, medical microbiology is also distinctive for its preventive applications. Vaccine development has resulted in the dramatic decrease of childhood infectious diseases such as measles and rubella. The eradication of smallpox worldwide and hopes for a similar outcome for polio have arisen as a consequence of the scientific developments in medical microbiology (Winslow 1950). On a more mundane level, rapid identification and typing of microorganisms has helped direct infection control operations in hospitals and communities afflicted by epidemics and outbreaks.

Relevance to Science and Religion

Medical microbiology has, from its inception as a scientific discipline, steered clear of religion. On the fringes however, medical microbiology insights, along with other advances in medical and scientific knowledge, have been used by scholars to propose explanations for phenomena

described in religious texts. For example, schistosomiasis was advanced as a possible explanation for the abandonment of Jericho in the 1970s, and various other microbiological causes were put forth to explain some of the ten plagues in Egypt. Schistosomiasis is a parasitic disease prevalent in developing countries in the tropics. It is caused by several species of flukes (*Schistosoma* sp.), which are carried by freshwater snails. People swimming in infected water may acquire either the liver or urinary forms of the disease, depending on which types of flukes are acquired.

Sources of Authority

This has evolved over time. Initially, the authorities in medical microbiology were prominent scientists such as Pasteur, Koch, and Martinus Beijerinck, who in the late nineteenth century established the principles and techniques for microbiological work that are largely still applicable today (Winslow 1950). Pasteur also developed vaccines to deadly diseases such as anthrax and rabies while Koch introduced various staining techniques and discovered the causative agents of tuberculosis and cholera in addition to the development of his famed postulates. Beijerinck is credited with the discovery of viruses and the development of enrichment techniques for culture, although he never worked on human diseases (Winslow 1950).

In turn, these men inspired others who had worked with them to continue their groundbreaking work, and the institutes that they had established – including the Pasteur Institute (founded 1887) – became important sources of authority for the specialty. But this was the golden age of microbiology (approximately 1870–1930), where microbiological work spread to different continents, and where an ever-increasing number of diseases were found to have causative microorganisms. Original work published in scientific peer-reviewed journals increased in number and quality, and these became increasingly important.

The discovery and development of antimicrobial agents by first Ehrlich and then Fleming

(penicillin) and successive others in the twentieth century shifted a significant part of the focus of medical microbiology toward clinical institutes and hospitals (Isenberg 2003; Winslow 1950). Professional healthcare and government organizations such as American Society for Microbiology, Centers for Disease Control (USA), Clinical Laboratory Standards Institute (USA), and Health Protection Agency (UK) published diagnostic and interpretive guidelines on medical microbiology that were increasingly used by healthcare professionals. This coincided with the advent of the internet and online publishing in the late twentieth and early twenty-first centuries, resulting in a few centralized authoritative institutes amid original published research that incrementally advance the specialty.

Ethical Principles

Medical microbiology, as with other specialties in medicine, is guided by the World Medical Association's Declaration of Helsinki. This is currently in its fifth revision (2000). Other important ethical guides include the Geneva Convention Code of Medical Ethics, which was adopted by the World Medical Association in 1949.

Key Values

The key values of medical microbiology are rapid and accurate diagnosis of microbial diseases, as well as understanding of microbial pathogenesis in order to improve outcomes in infectious diseases or prevent their spread. To this end, practitioners are called to adopt and use evolving technologies, and to remain aware of constantly emerging and evolving microbial pathogens.

Conceptualization

Nature/World

Nature refers to the natural and physical world, of which microorganisms form the largest part.

Interactions between humans and nature, particularly in new or unexplored environments, therefore result in interactions between humans and new microorganisms that may potentially cause disease.

Human Being

The human being is a biological being – a eukaryote – that is colonized by a diverse microbial flora. In other words, a human being is an organism with a membrane-bound nucleus within each of its cells. Animals and plants are eukaryotes, whereas bacteria are prokaryotes. Fungi, some of which are medically important and studied in medical microbiology, are also eukaryotes. These microbes may occasionally cause disease when the host immunological barriers are breached or fail.

Life and Death

Medical microbiology does not conceptualize life and death any differently from other medical specialties. In humans and other organisms, life is the presence of growth through metabolism, adaptation to the environment, and reproduction. Death is the loss of these processes, including the loss of physical organ functions. In medicine, the relatively new terminology of “brain death” – where brain activity ceases but other organ functions are maintained – remains controversial.

Two particular microorganisms challenge the conventional definitions of life and death. These are viruses (essentially genetic particles incapable of replication outside host cells) and prions (infectious particles composed of proteins only).

Reality

Reality is the physical material world.

Knowledge

Medical microbiology does not define or conceptualize knowledge differently from other scientific and/or medical specialties. In essence, it is the theoretical and/or practical understanding of a subject matter.

Truth

Truth is defined as being in accordance with facts and/or reality – a logical truth. As with other

scientific disciplines and in accordance with the formal theory of logic, truth is dealt with in a subjective and not absolute sense.

Perception

Perception is the state of being or becoming aware, understanding, and interpreting through the senses.

Time

Time is a fundamental quality used to sequence and define other events. This may be measured objectively.

Consciousness

Consciousness reflects the responsiveness of organisms to physical stimulus. It is unclear at this point if microbes possess consciousness.

Rationality/Reason

Rationality is the state in humans of having sound judgment and good conduct. Infections by microbes, particularly of the human brain, may cause this to be impaired.

Mystery

Mystery is accepted in medical microbiology, as in other scientific disciplines, as a temporary phenomenon that may be elucidated following the directed scientific research.

Relevant Themes

The concept of evolution is relevant for medical microbiology as regards “Science and Religion” engagement. That microorganisms evolve constantly is undeniable – the development of anti-microbial resistance and genetic shift and drift seen in certain viruses are the clearest indicators of such phenomena occurring.

Medical Sociology

Johannes Siegrist

Heinrich Heine-Universität Düsseldorf, Senior Professorship Workstress Research Life Science Center, Düsseldorf, Germany

Description

Medical sociology is one of the significant subdisciplines of general sociology. As a core social science sociology is concerned with the analysis of general principles and culturally varying processes of developing societal structures, institutions, and patterns of relationships among humans. Medical sociology (more recently often termed “health sociology”) applies the theories and methods of general sociology to the analysis of two main areas of inquiry: first, the social determinants of human health and health-related behavior, and second, the social organization of health care, health

professions, and their interaction with patients. The former area is termed “sociology *in* medicine,” due to its problem-oriented approach that integrates sociological and biomedical knowledge, whereas the latter area is termed “sociology *of* medicine” as it analyzes the health care system from a more distant perspective as part of a broader social system. Medical sociology evolved from general sociology in the first half of the twentieth century in the USA and in Europe, but received relevant input from sociological “founding fathers,” in particular Emile Durkheim (1858–1917) from France and Max Weber (1864–1920) from Germany. The former introduced macrosocial constructs to explain variations in suicide, and the latter developed a general theory of modernization of society, its institutions, and professions.

Self-identification

Science

Medical sociology has been, and continues to be, identified as a social science. As such, it meets the four essential principles of a scientific discipline: it disposes of a specific terminology to identify particular aspects of our reality (the social reality with relevance to health and health care), it applies established methods to collect empirical data, it accumulates descriptive knowledge on the defined aspects of reality, and it develops and applies theoretical concepts to explain and predict the phenomena under study.

As an empirical science, medical sociology uses quantitative and qualitative methodologies in collecting data and in testing research hypotheses. Distinct from natural sciences that are mainly concerned with general laws related to the natural world, sociology deals with a more flexible, man-made reality, the reality of culturally varying social systems, and therefore, its explanations are restricted to so-called middle-range theories with limited generalization.

Characteristics

Medical sociology is distinctive among other social and behavioral sciences in that it applies both macrosociological and microsociological approaches to the study of human health and health care. As an example of macrosociology, sociology *in* medicine explores the impact of socio-environmental and structural conditions on health, such as poverty, unemployment, or social disorganization. As an example of microsociology, it demonstrates how secure and gratifying social relationships in core areas of exchange, such as family or work, affect human health and disease, for example, via behavioral or brain-mediated (cognitive, emotional) processes.

As an example of macrosociology, sociology *of* medicine analyzes the process of professionalization of physicians in modern health care systems, whereas its microsociological study is concerned with the characteristics of the physician-patient relationship as a distinct type of social interaction. Distinct from psychology, this subdiscipline of sociology is essentially interested in the interaction between the opportunities and constraints provided by a societal structure to its members and the needs and motivations of individual members who are exposed to, but also actively shaping this structure.

Relevance to Science and Religion

At least three different topical links between science and religion are relevant to this discipline. First, health and illness, birth and death are existential experiences of human life, and these experiences are shaped by sociocultural norms and socioeconomic contexts. By analyzing this interplay medical sociology provides insights to religion, but also draws from religious experience, for example, in understanding human suffering and ways of coping with threat and anxiety. Second, religious experience was shown to have beneficial effects on health. Analyzing this link is an interesting and important scientific task for this discipline. For instance, research

demonstrated that balancing efforts with rewards in core human activities exerts favorable effects on health. Religion may provide rewards beyond the usual material or post-material values, or may enable people to become less self-centered in pursuing rewards. Third, health care provision and access to life-saving means is a scarce resource in most health care systems. Thus, fundamental ethical issues of distributional and procedural justice evolve in relation to issues of value of human life. The same holds true for advanced technologies and scientific progress in medicine. In all these instances, an intense dialogue between science and religion is needed.

Sources of Authority

As in most sciences, eminent personalities who developed substantial innovations in theory or in methodology are considered authorities, often forming specific traditions (“schools”) within the discipline. Established textbooks, peer-reviewed original scientific publications, standards of academic training, and regular public discourses (congresses, Internet, etc.) are essential prerequisites of a “sound” scientific development.

Ethical Principles

As in every science, this discipline is expected to observe the general ethical principles of searching and presenting the truth by using appropriate reliable and valid tools of analysis and of avoiding manipulation and all other sources of scientific misconduct. Moreover, research must avoid any noxious effects on humans involved.

Key Values

Most professionals of this discipline would agree that the most important value of this discipline is to contribute to a reduction of human suffering, in particular a reduction of social inequalities in health between and within populations. Scientific knowledge of this discipline is instrumental in

identifying, explaining, and reducing these inequalities. Equally, promoting health and well-being by means of identifying and strengthening protective socioeconomic and psychosocial conditions is considered a key value.

Conceptualization

Nature/World

This discipline assumes that knowledge about nature as derived from updated natural sciences can be taken for granted and integrated into sociological analysis where needed. Clearly, there are important unresolved questions about the origin and trajectory of the natural world and about the limitations of the human mind of dealing with nature. In contrast, “world” is considered by this discipline as a socially and cognitively constructed reality that is in constant flux and that to a large part can be dealt with in productive ways by human mind and action.

Human Being

Human beings are considered the result of an evolutionary process that resulted in a species characterized by several unique capabilities and behaviors that are closely related to the development of human brain and its coevolution with social structures. Yet, there exist many fundamental open questions about the specific qualities of human nature.

Life and Death

Valid knowledge about these fundamental processes comes from biosciences, chemistry, physics, etc., but sociology adds to this analysis a sociocultural dimension of meaning and practice rooted in belief systems and social norms. Again, fundamental questions about life and death remain unanswered by current science.

Reality

See “world” above: Reality is defined as the physical substrate of the world that is accessed by our sensory processes, our higher nervous system activity, and our actions. Importantly, by our thoughts and actions we are able to influence – and thus modify – the real world to a significant extent.

Knowledge

This discipline distinguishes two different types of knowledge: (1) Knowledge based on evidence or experience about real-world phenomena, either acquired via socialization and learning, or accessed via information media. This type of knowledge can be communicated between individuals via mutually shared signs, for example, language; (2) Knowledge as subjective experience or evidence of an individual accumulated over one's life trajectory. This knowledge is part of an individual's unique world and can only be accessed or communicated selectively and approximately. Sociology and its subdisciplines, including medical sociology, are particularly interested in the analysis of origins and consequences of unequal distribution of knowledge across society.

Truth

As in philosophy, this discipline distinguishes between logical and empirical truth. Logical truth relates to the conclusiveness of arguments derived from certain axiomatic statements. Empirical truth relates to the congruence of a statement with the fact it describes.

Perception

This discipline integrates the definition of perception provided by modern neuroscience, that is, sensory input from external and internal stimuli processed by the brain in part consciously, in part unconsciously.

Time

Time as ongoing change of everything in the real world has an objective duration that can be measured by physical instruments. It has also a subjective dimension related to the experiences and interpretations of individuals. In many instances a discrepancy exists between objective and subjective time evaluation.

Consciousness

As humans, we are able to perceive our world and ourselves and to be aware of these perceptions.

This higher nervous activity is absent during sleep or specific critical conditions of ill health, and is reduced in people with specific mental or neurological disorders.

Rationality

This discipline considers rationality as an evolutionary stable pattern of human thinking and acting that aims at understanding and solving problems in effective ways and at acting in accordance with consistent principles. Rational behavior anticipates the consequences of one's actions and, thus, involves the acting person's responsibility.

Mystery

In science, mystery is the area of the unknown, which eventually and gradually can be unraveled by scientific progress. However, there is a second meaning of "mystery" that delineates a particular type of experience, imagination, vision, etc., that seems to transcend any scientific, rational approach. In this latter sense, mystery is an important component of religious experience and practice.

Description

Medicine in Islam includes, firstly, a study of the history of Islamic medicine, the medicine practiced during the Islamic era stretching between the Greco-Roman Alexandrian times and the era of European Renaissance. Related to this first field of study is a subdiscipline in Islamic philosophy that serves to describe and clarify in objective, contemporary terms the methodological and philosophical principles that have guided the cultivation of medicine and other sciences in Islamic civilization.

Secondly, the term “Islamic medicine” also designates the currently reemerging concept of medical sciences as influenced and regulated by the worldview and ethical principles of Islam. As stated by Setia (2007), this meaning pertains to the subject matter of a discipline that serves to reformulate the concept of Islamic medicine and other sciences as a long-term creative research program dedicated toward a systemic reapplication of Islamic cognitive and ethical values to medicine, science and technology in the contemporary world (Setia 2007). This will involve critical integration of the scientific endeavor into the conceptual framework of the Islamic worldview and the concomitant explication of the cognitive, methodological, and axiological implications of such integration for present and future scientific research.

This operative redefinition of Islamic science as well as Islamic medicine will render it into a new overarching “paradigm” or “research program” pregnant with novel methodological and empirical implications (and hence, novel discoveries) for remanifesting the Islamic worldview in everyday individual and societal life through the vision and practice of a new, authentically Islamic science and technology geared first and foremost toward identifying and solving the true problems and satisfying the real needs of humanity.

Many Western authorities on history of medicine have acknowledged and documented the close relation and integration of medicine and other natural science, with the religion of Islam. This relation stems from the unique nature of Islam and its underlying unity in all domains of knowledge based on the Qur’anic concept of *Tawhid*, Oneness of God, and the most fundamental principle of Islamic epistemology. Islam, as a religion is distinguished by being a way of life that goes beyond the mere performance of rituals. The Arabic word for religion “din” appears in Qur’an, Islam’s Holy Book, in contexts that place it outside the purely ritual. Din in essence describes an integrated code of behavior, which deals with personal hygiene, at one end of the spectrum to the relationship of mankind with the natural order at the other. It provides a holistic approach to existence, it does not differentiate between the sacred and the secular and neither does it place a distinction between the world of mankind and the world of nature. The motivation provided by Islam for the study of natural phenomenon and pursuit of empirical knowledge is, thus, tremendous. This explains the harmonious relationship between epistemological dimensions of science and the Islamic worldview, as well as between ethical and societal dimensions of science and Shari’ah (the Islamic Divine Law).

As detailed by Bakar (2003), the word Islam refers not only to its normative teachings that allow for fresh interpretations but also to its culture and civilization as these dimensions have been manifested throughout Muslim history. If Islam is understood in this sense, then it has to be inclusive of its past intellectual culture,

of which medicine and science used to be an integral part. It is a position that is informed by a solid knowledge of the history of Islam the religion and Islam the civilization. This civilizational approach to the Islam and science discourse which is sensitive to tradition is based on the conviction that past formulations of the relationship between religion and science have an intrinsic value that make them relevant to contemporary attempts to arrive at the same conceptual goal. On the other hand, a discussion of Islam and medicine in the background of definitions rooted in the post-Renaissance understanding of religion in the Western world will be unrepresentative (Bakar 2003).

Several recent studies in the history of medicine illustrate that Islam's contributions were richer, more profound, and more lasting than was previously thought. As recent research has shown, there is a continuum between Islamic medicine and modern medicine. Science in Islam is not just a forerunner, something strangely distinct and distant, from science today but an integral part of modern science.

Focusing on the history of our surgical specialty, urology, we performed several primary-source studies utilizing the already published original medical works of 11 Islamic medical scholars who lived and practiced between the ninth and the thirteenth centuries.

Our study critically evaluated their contributions to the progress of not only urology but also other surgical and medical subspecialties. Their original works were compared with those of their predecessors and with those who came after them. Their influence on Medieval Europe and European Renaissance was traced, evaluated, and documented. Furthermore, original translations into English were made of relevant excerpts of all the works studied. The Latinized works of all those Islamic scholars (Figs. 1, 2, and 3) were available in Europe as early as the twelfth century, with their influence lasting until the eighteenth century as documented by Sarton, Cumston, and several other Western scholars (Sarton 1927; Cumston 1926).

Out of this long-term study, several original contributions to the progress of urology by those

Medicine in Islam, Fig. 1 A Latin edition of the Kulleyyat of Ibn Rushd and the Taisir of Ibn Zuhri; the first-ever example of joint authorship of a medical textbook (Printed in Venice in the year 1542, courtesy of Biblioteca Histórica de la Universidad Complutense de Madrid)

scholars during the Medieval Islamic era have been documented (Abdel-Halim 2008). This includes contributions to the progress of anatomy, physiology, pathology, clinical urology, therapeutics, operative urology, and instrumentation.

Our results also confirm that those scholars of the Islamic era were not mere compilers or sheer transmitters of Greco-Roman medical literature. On the contrary, they critically reviewed the translated heritage of previous civilizations rejecting what is superfluous and accepting only what proves to be true. They added original contributions to the progress of medicine and surgery and pioneered new fields of medical

Medicine in Islam, Fig. 2 A Latin edition of Ibn Sina's Canon of Medicine printed in Rome in 1593 (Courtesy of Biblioteca Histórica de la Universidad Complutense de Madrid)

knowledge and practice such as medical ethics, medical education, medical certification, health education, preventive medicine, social medicine, hospitals and hospital training, mobile hospitals, medical-practice quality control, clinical medicine, differential diagnosis (Fig. 4), experimental medicine, experimental surgery, beginnings of specialization, ophthalmology, pharmacology, and use of anesthetics.

Over the last three decades or more and coinciding with the beginning of the fifteenth Hejri century, an increasing interest in Islamic medicine has been noticed in different parts of the Islamic world as well as in few Western research centers. This scientific activity that seemed to be a product of the Islamic revival movements in various Muslim countries took the form of seminars, conferences, books, and other scientific publications organized and

Medicine in Islam, Fig. 3 Another Latin edition of Ibn Sina's Canon of Medicine printed in Louvain in 1658 (Courtesy of the Koraes collection, Koraes Central Library of Chios)

published through individual and organizational scholarly efforts.

This ongoing contemporary discourse on Islamic medicine, Islamic science, and Islamization of knowledge in general is enriched by the contributions of many scholars in different parts of the Muslim world as well as in the West. Among those who significantly contributed to the advance of this reemerging discipline are Al-Attas, Nasr, Bakar, Al-Faruqi, Golshami, Muzzafar, Setia, Kamali, Kazi, Sardar, Kalin, and many others. They all provided important background knowledge that helped in the construction and growing understanding of the concept of Islamic science including medicine. However, what remains and is essential for this Islam-science discourse to move forward is

Medicine in Islam, Fig. 4 The opening page of a manuscript of the first-ever book written on differential diagnosis: *Kitab Ma Al-Fariq, Kalamun Fi Al-Furuq Bain Al-Amrad* (A discourse on differential diagnosis) by Al-Razi (Rhazes)

the actual emergence of a scientific tradition based on the foundational principles of the study of nature anchored in the Qur'an and the Prophet's Tradition (Sunnah).

Several scholars formulated their viewpoints on how to implement the concept of Islamic science. According to Setia (2007), the true operative essence of Islamic science including Islamic medicine is that it has to be involved in an unapologetic, proactive construction of empirico-conceptual frameworks for interpreting and interacting with the world in a way that is self-consciously inspired by, and hence, in harmony with, the ethico-cognitive principles of Islam. For that purpose, Setia formulated a proposed Islamic Science Research Program (ISRP). It consists of an unchanging core metaphysical component underpinning the

program and a surrounding network of auxiliary explicative theories and hypotheses for relating the metaphysical abstract core to the concrete physical world. The role of the network of auxiliary theories is to provide directions for the conceptual clarifications and empirical investigations of various aspects of this permanent metaphysical core by relating them to corresponding aspects of the physical world. In other words, it is in this creative middle circle where the discursive reason (*fikr*) and contemplative intellect (*'aql*) mediate between the book of revelation and the book of creation (Setia 2007).

Setia, also, emphasized the role of the twin Qur'anic cognitive principles of *tabayyun* (investigation, scrutiny) and *burhan* (proof, evidence) in implementing the concept of scientific objectivity in the ISRP with respect to cultivating a critical attitude toward contemporary science. He stated that it will be irresponsible to take reports of promising new methods, discoveries, and techniques at face value without undertaking investigation (*tabayyun*) into the often hidden underlying context of these reports and ascertaining their empirical adequacy (*burhan*) and "epistemological autonomy" (*al-istiqlal al-'ilmi*) from powerful forces geared less toward global scientific enlightenment than narrow political economic enrichment (Setia 2007). Creative understanding and practice of *tabayyun* and *barhanah*, as practiced before by the Medieval Islamic scholars, will help Muslim scientists to separate the wheat from the chaff of Western science and incorporate it into the ISRP.

In this context, further help can be obtained by undertaking evidence-based medical research into the well-documented but largely neglected vast corpus of the very successful 1,000 years old Islamic cosmopolitan medical tradition.

Cognitive evaluation and ethical evaluation are both intrinsic to the scientific enterprise in Islam, as is quite evident in the studied scientific methodology of the Medieval Islamic medicine. The realization that scientific objectivity and methodological probity are not possible without concomitant ethico-moral integrity has been growing in the West and is now moving more

toward the Islamic position thus allowing room for mutual constructive engagement on this important metascientific issue.

Self-identification

Science

Islamic medicine self-identifies as a science. This is well documented by Western authorities on history of medicine who studied the medicine of the Islamic era between the eighth and the fifteenth century. As stated by Cumston, the majority of the orientalist who have studied the works of the Arabs admit that long before Roger Bacon, they were in possession of that method which later on led to so many discoveries. Speaking of the school of Baghdad, he quoted Sedillot (*Histoire des Arabes*, Paris, 1854) as saying *“what specially characterized the Baghdad school at its beginning was the truly scientific spirit which presided over all. To go from the known to the unknown, then from the effects to the causes, and only to admit as true what had been demonstrated by experimental work; such were the principles taught by the masters”* (Cumston 1926). Similarly, in his classic work on the intellectual development of Europe, John William Draper acknowledged Europe’s scientific obligations to Islam (Draper 1863).

The Islamic system of medicine, well established as a discipline for over 800 years, was constructed in a logical, scientific, and regular manner, taking the consecutive steps of first translating all the works of the predecessors, followed by critical evaluation of those works, rejecting what is superfluous and accepting only what proves to be true. Then original contributions started and flourished.

From the days of Al-Razi (Rhazes; 865–925 AD) and onward, the medical scholars of the Islamic era were keen on direct observation and experimentation. Ibn Al-Nafis, the thirteenth-century Muslim scholar emphasized that *“as regard the function of organs, we rely only on what is dictated by investigative observations and accurate research; Not caring whether it*

conformed with, or differed from, the opinions of those who came before us.” Therefore, more than 600 years before the time of Vesalius (1514–1564), the interest and experience of the Muslim scholars in the study of anatomy led them to contribute to the advance of this important medical science by correcting many of Galen’s erroneous anatomical concepts. Ibn Al-Nafis, like his predecessors in the Islamic era, critically appraised the views of those who came before him in the light of his own experimentation and direct observations. Accordingly, in his book *Sharh Tashreeh Al-Qanun* (A Commentary on the anatomy of Ibn Sina’s Canon), we find the first correct description of the pulmonary circulation. He also laid the seeds of the proper understanding of the systemic greater blood circulation. Ibn Al-Nafis was also the first to describe the coronary vessels and the true concept of the blood supply of the heart. Those discoveries of Ibn Al-Nafis were translated from Arabic to Latin by the Padua-University-professor Andreas Alpagus; the translation was printed in Venice in 1547. Six years later, Ibn Al-Nafis’ description of the pulmonary circulation appeared in the *Christianismi Restitutio* of Servetus and, in 1555, in the second edition of the *De Fabrica Humani Corporis* of Vesalius. Similar descriptions were also given by Valverde in 1554, Columbus in 1559, Cesalpino in 1571 then, finally in 1628 by Harvey (Abdel-Halim 2008).

Furthermore, the presence of anatomical drawings within medical textbooks is a trend that started and flourished in the Islamic era reflecting the role of direct observations and experience. During the whole of the Islamic era, with the increase in practical experience, the illustration of anatomical findings continued to progress in quality and in fine details (Abdel-Halim 2008) (Figs. 5, 6).

Another example of the originality and sound scientific nature of the medieval Islamic medicine is the twelfth century Ibn Zuhri (Avenzoar)’s application, for the first time, of experimental methodology in evaluating new or controversial surgical procedures. He performed the operation of tracheotomy on

Medicine in Islam, Fig. 5 The drawing of the cross section of the brain and the eyes made by the thirteenth century Khalifa ibn Abi Al Mahasin Al Halaby (from Aleppo) in his book *Al Kafi Fi Al-Kuhl* (The Book of Sufficient Knowledge in Ophthalmology)

a goat in order to confirm the safety of the operation and disprove its condemnation by the Greco-Roman scholars. This unique experiment represents a further step in the development of the experimental school started by Al-Razi of Baghdad in the ninth century, who is known to have given monkeys doses of mercury to test it as a drug for human use. Ibn Zuhr's application of an experimental animal model to a clinical problem was the forerunner of the method by which many current surgical procedures were developed.

The investigative mind and reliance on experimentation in seeking evidence during the Islamic era is also represented by the post mortem examinations done on sheep by Ibn Zuhr in the course of his clinical and therapeutic research on ulcerating diseases of the lung.

Religion

Islamic medicine is the practical application of concepts of Islamic belief based on the Divine Revelation contained in Qur'an and explained in Sunnah. Both forms of revealed knowledge and their value system of Islam strongly support observation, inductive reasoning, and experimentation in the study of natural phenomenon. Search for truth is the method of Islam, and therefore, pursuit of scientific knowledge strengthens the faith of the believer. The quest of knowledge, creativity, and innovation has a sanction of the Holy Qur'an and is extolled by the Holy Prophet. It must, therefore, be pursued vigorously and with full commitment and dedication. One of the Prophet's main prayers was "O my Lord, increase me in knowledge." History is witness to the fact that Muslim philosophical thought and scientific knowledge of its golden period had essentially a moral and religious base.

According to Sarton, Cumston, Sedillot, and other Western medical historians, with the spread of Islam in the seventh century AD, a great revival of the sciences took place in the Islamic empire; knowledge of medicine flourished and acquired a truly scientific spirit, and doctors were highly esteemed (Sarton 1927; Cumston 1926). As stated by Guthrie, the progress in medical knowledge during the Islamic era was motivated and inspired by Divine Revelation. In documentation for that statement, Guthrie cited the translation of an authentic prophetic tradition saying: "O servant of God, use medicine because God has not created a pain without a remedy for it" (Guthrie 1945). Islamic medicine was stimulated by the concepts of faith. Learning and practicing medicine is an act of worship. Wisdom is highly appreciated and always sought for. In most of the Muslim countries, up till very recently, before the spread of the modern word "doctor," the physician's commonly-used title was "Al-Hakim" meaning in Arabic "the man of wisdom."

According to Castiglioni, this historical period of Islamic medicine, which lasted more than seven centuries, coincided with the most flourishing period of Islam. Likewise,

Medicine in Islam,

Fig. 6 Anatomical drawing of the maxillary sutures in one of the original manuscripts of Ibn Al-Nafis' book Sharh Tashrih al-Qanun (a commentary on the anatomy of Ibn Sina's Canon)

مساوية للتي للمثلث^(٥) عند طرف المنخر في تلك الجهة وتلك حادة ، وكذلك هذه . فتكون التي في ذلك العظم عند طرف المنخر منفرجة لأنها مع السفلية مثل قائمتين .
والله ولي التوفيق^(٦)

emphasizing the religious context of medieval Islamic science, Sarton said: "How could we reach a correct understanding of Muslim science if we did not fully grasp its gravitation around the Qur'an?" Medieval theology, he noted, was the core of science as well as the prop of religion. Science is positive knowledge, but scholarly inquiry cannot be restricted to the modern Western definition of positiveness. Medieval scholars (both Muslim and Christian) regarded theology as positive knowledge (Sarton 1927).

In Islam, the human body is a source of appreciation, as it is created by Almighty Allah (the God). Hence, all activities contributing to the well-being and preservation of health as well as the relief of sufferings of individuals and societies are virtuous acts of worship and essential religious duties. Muslim physicians, therefore, came to look upon medicine as the science by which the dispositions of the human body could be discerned and to see its goal as the preservation of health and, if health should be lost, assistance in recovering it (Fig. 7).

The close integration and unity of knowledge between Islam and medicine is also evident in the development and spread of health education during the Islamic era. Health education has always been an integral element of Islamic teaching, and its spread was inextricably linked with the spread of Islam itself (Figs. 8, 9 and 10).

Another example of the unity of medical sciences with Islamic faith is the statement of Ibn Rushd (Averroes, 1125–1198): "Anyone who practices anatomy will increase his faith in Allah." This is of particular importance because he was, at the same time, the Grand Qadi (chief magistrate) of Cordova and a well-known authority on Islamic jurisprudence in the whole Muslim world then and up till now. Accordingly, contrary to several contemporary medical historians, the practice of dissection for medical teaching was not prohibited in the religion of Islam (Abdel-Halim 2008).

Furthermore, the chapter devoted for physiology in the encyclopedic book Al-Mukhtar Fi Al-Tibb authored by Muhadhdhabul Din

Medicine in Islam, Fig. 7 A page from an original manuscript of Al-Zahrawi's book Al-Tasrif showing the beginning of the first volume. It starts with a citation of Al-Razi's definition of medicine: "medicine is preserving health unto healthy individuals and returning it to the sick within the limits of human abilities"

Al-Baghdadi (1117–1213) was titled the Gained Benefits of the Wisdom of Creation, and likewise, the chapter on Embryology was titled the Creation of Human Being. This example shows how Islamic faith and medicine were closely integrated in the minds and hearts of the Medieval Islamic medical scholars (Abdel-Halim 2008). They had no conflict at all in

Medicine in Islam, Fig. 8 The cover page of an original manuscript of "kitab muntakhab min kitab al hawi" (Selections from the Continens), a compilation meant for the spread of health education to the public. As stated by the author, he was inspired to write this book because God said in the Holy Qur'an: "Whosoever saves a human life, saves the life of the whole mankind" and also because of the Prophet's saying: "The best among people is the most devoted to their benefit"

their minds between religion and science. Indeed many of them were, also, pioneers in religious sciences.

Characteristics

The following distinguishing features of Islamic medicine as practiced during the Islamic era are evident and well documented:

- Motivated and inspired by Divine Revelation.
- Ethically based on values from Divine Revelation.
- Exalted the soul, the mind and the body at the same time.
- Constructed on a regular scientific way.

Medicine in Islam, Fig. 9 A page from the manuscript of “kitab muntakhab min kitab al hawi” (Selections from the Continens) shown in Fig. 8. The text shown is the author’s statement enjoining a sick person to seek treatment and maintain the body in good health because it is his means for faith and knowledge being the abode for the honored self and revered soul and it is the way to obey the divine commandments, acquire courage, and achieve a good life here and hereafter

- Strongly opposed to magic and quackery. The Prophet stated that “*If anyone carries out medical treatment, yet previously he was not known as a medical man, then he takes the responsibility*” (Johnstone 1989).
- Also, derived from “the medicine of the Prophet” is the primary attention given to preservation of health and prevention of disease (Johnstone 1989).

Relevance to Science and Religion

A major factor in the misuse of modern science and technology for destructive ends is its supposed value-neutral framework. The renaissance of science and learning in Europe was accompanied by a separation of the religious and the

Medicine in Islam, Fig. 10 A page from an original manuscript of the thirteenth-century book “Pearls of Prophetic wisdom for guidance on rules of medicine.” The title shown on this page is “a section on what is narrated on enjoining people to study medicine and the command to seek treatment”

secular, due to the peculiar conditions then prevailing. Knowledge has increasingly come to perform a utilitarian function, whose ends are determined largely by the prevalent and dominant distribution of societal power. Modern science, mistakenly based on the separation of the secular from the religious, has cut off its moral mooring. The world needs to rethink the assumptions that led to the creation of this value-neutral framework.

According to Patricia Marshall, the current dissatisfaction with the limitations of the analytical philosophical utilitarian approach to bioethics has led recently to explorations of religion-based philosophies with increased attention to moral phenomenology and a recognition of the importance of social, cultural, and historical determinants that shape moral questioning (Marshall 1992).

The highly integrated and holistic framework of Islamic science including Islamic medicine provides an alternative model, which permitted the growth of science and learning as well as protected society from its misuse.

There are so many verses in the Holy Qur'an and many sayings of the Prophet that are highly relevant to contemporary controversies in medical ethics, bioethics, as well as ethics of modern science and technology.

Furthermore, as stated by Bakar, unlike the modern trend of easily falling into the pitfall of reductionism, the Muslim search for premises has usually been guided by more holistic views of reality and knowledge. The result is a more solid intellectual foundation for sciences which also embraces issues beyond the domain of applications to include other aspects of the societal dimension of knowledge (Bakar 2003).

There is, also, a great need to revise the way university science and medical students are educated so that they know how to integrate their scientific knowledge and expertise into the more fundamental and higher goals of human life and thus avoid the destructive pitfalls of scientism. True science is beneficial knowledge (al-"ilm al-nafi") that is geared toward serving rather than subverting these higher, human goals.

Furthermore, there is a lot to learn from the experience of the Islamic medical scholars who developed their own original school of knowledge and practice more than 1,000 years ago. The way they critically evaluated cultures and civilizations before and around them, in the light of their own experience, rejecting what is superfluous and accepting only what proves to be true, is a good example for scientists today to stop blind imitation and lead the way for originality, innovation, and new inventions.

The study of the history of Islamic medicine will be also rewarded by progress in the fields of bioethics, medical ethics, ethics of medical education, ethics of experimental research, philosophy of medicine, psychological and mental health, care of the terminally ill patients, social medicine, holistic medicine, care for the environment, nutrition and many other areas related to public health and health services.

Moreover, there is a lot to learn from medieval Islamic medicine in relation to its greater emphasis on the art of maintaining health and care to prevent illness. Another lesson is that the least we use drugs the better. The illness that can be remedied by regulating diet should not be treated by medicines, and what is relieved by a simple medicine should not be treated by a compound drug, whereas surgical intervention should always be kept as the last resort. Furthermore, the vast experience of the medieval Islamic scholars well recorded in hundreds of extant Arabic works on pharmacy constitutes a buried treasure of information and provides a range of topics for modern pharmacological research bound to enrich our present day pharmacopoeias with simple and safe herbal medicines.

Paying attention to spiritual as well as bodily health will, also, help us to minimize and control the high incidence of psychosomatic disease complicating the spiritual deprivation of our contemporary materialistic way of life.

Sources of Authority

With regard to the ethical and societal aspects of Islamic medicine, the sources of authority are the moral (akhlaq) and legal (ahkam) codes derived from Qur'an and Sunnah. Akhlaq refers to morals, the second part of the Islamic teachings (second to "aqaid, doctrines) relate to the commands and teachings relating to the spiritual and moral characteristics of human beings, such as, justice, God-fearing (taqwa), courage, chastity, wisdom, endurance, loyalty, truthfulness, trustworthiness, etc., and prescribe "how" a human being should be. Ahkam is the Law, the third part of the Islamic teachings (third to "aqaid, doctrines and akhlaq, morals). It comprises the issues relating to practice and the correct manner of performing acts. Within this metaphysical and ethical framework, it will be easy to accept, assimilate, integrate, and advance any subject matter the truth of which has been confirmed by critical evaluation, experience, and experimentation.

Ethical Principles

The moral part of Islamic teachings (akhlaq) constitutes the commands and teachings relating to the spiritual and moral characteristics of human beings, such as justice, God fearing (*taqwa*), courage, chastity, wisdom, endurance, loyalty, truthfulness, trustworthiness, etc., and prescribes how a human being should be.

In an Islamic context, the Qur'anic term *khuluq* is closest to the term "ethics." (The first independent work on medical ethics was authored by Al-Razi under the title of *Khuluq Al-Tabeeb* (The Physician's Good Manners). Ishaq ibn Ali al-Ruhawi who lived around 1200 AD used the title *Adab al-Tabib* for his famous book on medical ethics. The word "Adab" is closely related to "Kuluq"; hence, the title here also means the physician's good manners.) Also, some other terms referring to fundamental ethical principles referenced from Qur'an and describing the concept of good are *khayr* (goodness), *birr* (righteousness), *qist* (equity), and *'adl* (equilibrium and justice). The Islamic moral philosophy served as a basis for defining and suggesting solutions of the ethical and moral problems facing individuals in all various walks of life whether they are professionals, scientists, practitioners, businessmen, or workers.

Islamic medical ethics is integrated within the framework of *Ihsan* (good personal conduct), that aspect of Islamic creed, which is, described as the act of worshipping Allah as if you see Him, knowing that even if you do not see Him, He sees you. Consequently, the strict adherence to ethical principles becomes inspired and internally monitored by the love to do what is pleasing to Allah, who is ever present, ever watchful.

Key Values

- Islam emphasizes on the sanctity of human life and considers access to health care as a fundamental right of the individual.
- Islam emphasizes on the respect of a person's rights and dignity.

- Another main principle is the emphasis on seeking a cure. This is further emphasized by the fact that three of the goals of the Islamic Shari'ah are the protection and preservation of life, intellect, and progeny. The other two are the protection of property and religion.
- The physician is an instrument of God's mercy on earth. So are the scientist and every individual in his own career.
- Five key values govern Islamic ethics: unity, equilibrium, free will, responsibility, and benevolence.
- In the framework of *Ihsan*, the above-mentioned principles and values have lasting effect both on the personal, professional, and day-to-day activities of individuals.

Conceptualization

Nature/World

Nature/world has been created for a purpose and is blessed with a meaning. Man is entrusted by God to take good care of nature for himself and future generations, as well as for animals, plants, and environment.

Human Being

Human being is created by God and has a transcendental nature. Man is dignified. He is made the center of the Universe. He is not completely part of nature. Dignity and nobility are part of each human being's birthright.

Life and Death

Life is a divine gift from the Creator. The first leg of its journey starts in a womb then from the darkness of the womb to the light of this present world. With death, the soul, then, leaves the body, but life continues in a different form until the Day of Judgment when it will rejoin the recreated body and come out from the darkness of the grave to the light of the hereafter, the final eternal abode.

Reality

To accept the metaphysical dimension of reality is an integral aspect of the Islamic worldview,

and the Qur'an clearly demands that. In a similar vein, to acknowledge the reality of the human psyche and thought is just as natural as acknowledging his physical existence. This is bound to be ultimately a wholesome and a more meaningful approach to the understanding of reality and a sound foundation, therefore of a valid epistemology.

Knowledge

The Islamic concept of knowledge encompasses transcendental knowledge as well as knowledge that is based on sense perception, observation, experimental knowledge and rationality. Islam also lays emphasis on beneficial knowledge that advances human welfare and seeks to utilize the resources of the universe for sound and beneficial purposes.

Truth

The fundamental truth and essential message in life is so expressively placed before humanity in the Qur'an and Sunnah. It is the same message that had been revealed to all other Prophets during the long course of human history.

Perception

Human perception and knowledge are of two kinds: perception by the senses and knowledge through the contemplative intellect. It is important to have a philosophical framework through which to give meaning to the data of sense perception and a sense of coherence to our understanding of reality, science and religion. Islam's perception of knowledge is thus value-oriented and informed by ethical and theological concerns.

Time

Time is life. It goes on for a fixed term in the present world then continues to eternity in the hereafter.

Consciousness

Muslim religious consciousness is essentially the consciousness of the unity of God. The scientific spirit is not opposed to this religious consciousness, since it is an integral part of the latter.

Rationality/Reason

In Islam, the word "intellect" (reason) is used in its traditional sense, namely, as related to contemplation. The modern connotation of the words intellect and reason as logical analysis or discursive thinking is the result of the emptying of their metaphysical content. The attitude these words imply toward nature is the one that Goethe was to deplore as late as the early nineteenth century – that attitude that resolves, conquers, and dominates by force of concepts. It is, in short, essentially abstract, while contemplative knowledge is at bottom concrete.

Mystery

With regard to the origin, purpose, and end of life, the Divine Revelation in Qur'an and in Sunnah left no unsolved mysteries in the human mind. The Creator also provided humankind with the mental tool to discover, understand, and resolve mysteries of nature.

Relevant Themes

The major medieval scientific and medical treatises, usually quite lengthy, still await reliable translations and editions, and a great deal of potentially important material lies unexamined. Furthermore, the latest research and the last few years have seen revolutionary findings that pushed forward the date for the beginning of a decline in Islamic science well into the sixteenth century. Moreover, as documented by Saliba, in the field of astronomy, and many others in the field of medicine, it is becoming more and more apparent that the scientists who were responsible for the production of original scientific discoveries in Medieval Islamic science and Islamic medicine were mostly religious men at the same time and religious scholars in their own right (Savage-Smith 1988). Accordingly, works exploring the relationship between science and religion and between Arabic science and Western science have to be rewritten in light of these new findings.

Description

Since its beginnings in the first decades of the nineteenth century, the scientific study of meditation had a strong focus on physiological changes in practitioners. After a couple of initial

electroencephalographic (EEG) studies of yogis and Zen monks conducted in India and Japan in the 1950s and 1960s, meditation research flourished in the 1970s with the popularity and spreading of Transcendental Meditation® in the West (a concise outline of major research strands can be found in the bibliography by Murphy et al. 1997). The observed calming effects on peripheral physiology – e.g., respiration and heart rate, blood pressure, muscle tone, skin conductance – and on the central nervous system supported the notion of meditation as a technique to evoke a “relaxation response” that could be employed in mundane and clinical settings to counteract stress. In addition, phenomenological analyses of subjective experiences during meditation and research on personality changes in practitioners underscored the potential of meditation to induce altered states of consciousness and foster self-development (for review, see West 1990).

Over the last 2 decades, the number of studies in the field of meditation research has sharply increased. To some degree, this upsurge is driven by the development of modern brain imaging techniques, in particular magnetic resonance imaging (MRI). The various meditation techniques that have been investigated with these techniques differ with respect to the object of focus, the width of attentional focus, and effortful self-control versus passive stance. Concordantly, EEG and functional MRI studies have reported a broad variety of findings providing a complex picture of effects and interpretations (for review, see Cahn and Polich 2006; Lutz et al. 2008).

Another reason for the sharp increase in the number of research studies on meditation over the last 2 decades is the increasing interest in mindfulness meditation. Standardized clinical programs that include training in mindfulness meditation like mindfulness-based stress reduction (MBSR) and derived interventions for numerous mental disorders have shown to be effective in ameliorating symptoms and promoting health (Fjorback et al. 2011). In this field of application and research, meditation exercises

are uncoupled from their traditional religious contexts and conceptualized as certain types of mental training that can be used to enhance distinct self-regulation skills – e.g., relaxation, concentration, and equanimity. The remainder of this entry focuses on mindfulness meditation and the mechanisms of action that have been described in the recent literature.

Mindfulness meditation, the practice of nonjudgmental awareness of experiences in the present moment, has been found to produce beneficial effects on a number of psychiatric, functional somatic, and stress-related symptoms and has therefore increasingly been incorporated into psychotherapeutic programs (Baer 2003; Grossman et al. 2004). Research has established that mindfulness meditation positively influences aspects of physical health, including improved immune function, reduced blood pressure and cortisol levels, and increased telomerase activity. Furthermore, a large body of research is beginning to document the efficacy of mindfulness-based therapeutic interventions in the treatment of a number of clinical disorders, including anxiety, depression, eating disorders, chronic pain, and substance abuse. Aside from investigating the effects of mindfulness practice on disorders, meditation research has also begun to investigate the positive effects of the practice on psychological well-being in healthy participants and its effects on cognitive functioning.

Along with the many reported positive implications of mindfulness arises the following questions: How does mindfulness work? What are its mechanisms? The existing body of research points to the fact that an array of distinct but interacting mechanisms might be at play in producing the benefits of mindfulness meditation practice. Recent theoretical frameworks have suggested that meditation might work through several mechanisms, including (1) attention regulation, (2) body awareness, (3) emotion regulation, and (4) change in perspective on the self (Hölzel et al. 2011). These components have been suggested to interact closely to constitute a process of enhanced self-regulation.

Attention Regulation. Illustrating the effects of repeated practice of focused attention during meditation practice, meditators report that they are able to focus their attention for an extended period of time. In accordance with such self-reports, a number of studies have empirically documented enhanced attentional performance in meditators (Lutz et al. 2008). The anterior cingulate cortex is the brain region that enables executive attention. In line with the behavioral findings of improved attention, several neuroscientific studies have reported the anterior cingulate cortex to show functional and structural changes following meditation training (Cahn and Polich 2006).

Body Awareness. Body sensations are a common object of attention during meditation, and practitioners often report improved capability for body awareness, but empirical studies testing that claim are mixed. Studies assessing performance on a heartbeat detection task found no evidence that meditators showed superior performance. Tactile acuity, however, has been shown to be superior in experienced Tai Chi practitioners and to be improved in experienced meditators. Findings from the mindfulness neuroscience literature point to changes in the function and structure of brain regions related to body awareness, such as the insula, which is involved in interoceptive awareness.

Emotion Regulation. A growing body of literature suggests that mindfulness practice results in improvements in emotion regulation. Studies from the field of meditation research have addressed improvements in emotion regulation through a variety of approaches, including experimental, self-report, peripheral physiological, and neuroimaging data. For example, it has been shown that mindfulness practice reduces interference from negative emotional images in solving a response task, suggesting that mindfulness meditation enables subjects to better regulate

their emotional responses. Several theories have suggested that the enhanced emotion regulation capacities seen in meditators are achieved through strengthening of positive reappraisal processes. Other theories have suggested that it might work akin to exposure therapy and facilitate extinction of maladaptive emotional responses. During emotion regulation, prefrontal control systems in the brain modulate emotion-generative limbic structures, such as the amygdala. Modification of this fronto-limbic network through meditation practice has been suggested by functional and structural MRI studies.

Change in Perspective on the Self. The essence of Buddhist psychology lies in the teaching that there is no such thing as a permanent, unchanging self. Rather, the perception of a self is a product of an ongoing mental process. The process of a repeatedly arising sense of self becomes observable to the meditator through development of meta-awareness. According to Buddhist philosophy, a change in perspective on the self is the key in the process to enduring forms of happiness. Whereas more advanced meditation practices are required to experience a dis-identification from the static sense of self, a de-identification from some parts of mental content is often experienced even in the earliest stages of meditation practice. Self-report studies have begun to document the experienced changes in perspective on the self following meditation. Those studies documented a more positive self-representation and higher acceptance of oneself, as well as the development of an observer perspective. Neuroimaging studies of mindfulness meditation have demonstrated that brain structures that support self-referential processing are structurally and functionally impacted by mindfulness meditation, including the medial prefrontal cortex and posterior cingulate cortex.

The above described components, attention regulation, body awareness, emotion regulation,

and change in perspective on the self, are presumably highly interrelated, constituting a process of enhanced self-regulation.

Memory

Hans J. Markowitsch

Psychology, University of Bielefeld, Bielefeld, Germany

Description

Memory is a universal attribute of animals and is sometimes even used with reference to plants and machines. Consequently, memory is an important concept for many scientific disciplines from the neurosciences and psychology over physics to history and the humanities. In the context of animals (including human beings), it implies the storage of ontogenetically acquired information in neuronal structures so that it may be recalled in the future. Nowadays, memory is split into systems and processes. The systems are based on time and content. The most universal distinction is that between short-term and long-term memory. Contrary to its common use, the neurosciences limit short-term memory to seconds or minutes at most and to the acquisition of a very few bits of information (4–7). Long-term memory is then everything extending in time or bits of short-term memory and consequently includes lifelong memories as well. The content-based division of memory uses simple memory systems, relying on mechanical or motor-related acts (e.g., riding a bike, skiing, playing piano) (“procedural memory”), on the repetitive appearance of subconsciously acquired material (“priming”), on percepts (e.g., of an apple or a cherry) (“perceptual memory”), on our general knowledge (world knowledge, school knowledge) (“semantic memory”), and on autobiographical events or episodes which have a distinct time and place connotation, which are based on the conjunction of subjective time, the autonoetic consciousness (“self-awareness”), and the experiencing self (“episodic-autobiographical memory”). The processes imply a conscious (explicit) or an unconscious (implicit) acquisition

of information. The sketch illustrates the complexity of memory as seen at present (Fig. 1).

Self-identification

Memory is both viewed as a science and is subject to intensive, methodologically complex investigations and is seen as an everyday attribute of individuals – exemplified by expressions “to have a good (or to have a bad) memory” of certain events or episodes that happened in life. Both science and common sense see memory as most important for a successful interaction with the world. Ewald Hering, a physiologist, formulated roughly 140 years ago: *“Memory connects innumerable single phenomena into a whole, and just as the body would be scattered like dust in countless atoms if the attraction of matter did not hold it together so consciousness – without the connecting power of memory – would fall apart in as many fragments as it contains moments.”* So, Hering expressed in short words how dependent we are on our memories and how memory distinguished us from a world in which only the present exists – the world of animals. Large amounts of human memory are conscious (“autonoetic”), allow us to make mental time traveling, and make us humans to creatures that base their future on their past. Nevertheless, implicitly stored rudiments of time-based memories can be found in animals as well. In fact, it is quite obvious that memory evolved to increase the survival of individuals and species. Knowing that a plant or an animal is eatable or is toxic prolonged the life of an individual, and knowing that whether the smell of another individual or of an area in the environment indicates danger of being attacked or indicates the possibility of sexual intercourse increases the life of a species.

Memory is consequently a most important in the life sciences but also in culture. Not to repeat the errors of past generations evolves and strengthens humankind and therefore also leads to a better and more successful life of an individual. The possibility to find and define rules of memory and to identify false memories, memory distortions, and memory disturbances, in general,

makes the investigation of memory one of the most important scientific disciplines. A more recent expansion of this field lies in the possibilities to trace memory performance to brain performance: To investigate and unravel the conditions of successful and of impaired memories has become a major endeavor of scientific enterprises. This is done both by studying subjects with brain damage and subsequent impairments as well as by applying modern functional brain imaging techniques which allow to view the acting neural networks engaged in particular memory processes such as successful or unsuccessful processes of encoding, consolidating, storing, or retrieving memories. By doing so, it also becomes possible to develop and suggest strategies and techniques for memory repair, for memory improvement, and for providing clues that prevent a deterioration of memory.

Characteristics

Memory is both a universal attribute of mankind and is seen as an everyday experience, and memory is special, as it provides the bases for an ontogenetic and phylogenetic development of individuals and societies and consequently also of culture and culture-based traditions, such as religion. Importantly, memory is a feature or concept that has strong affinities and interactions with other components of behavior, such as attention, concentration, emotion and affect, executive functions, and cognitive flexibility.

Relevance to Science and Religion

Mnemonics – the rules to improve and strengthen memories – are of interest to both individuals and societies. There is a tradition from the song lines of Australian aborigines over medieval memory culture up to oral history. Furthermore, memorizing pattern, such as repetition and colorization by rhythmic and musical recitations, has a strong tradition in various religions (Buddhist/Lamaist praying, Christian Gregorian songs, Judaic psalm prayers) for memorizing and deeply encoding

Memory, Fig. 1 Sketch of the five content-based long-term memory systems used presently. The systems develop phylo- and ontogenetically from left to right. The first two (procedural memory, priming) are considered to be anoetic (i.e., do not require conscious reflection for being retrieved), perceptual memory and semantic memory are considered to be noetic systems, requiring awareness and reflection, and the episodic memory system requires autoeotic consciousness, that is the ability to reflect upon oneself and to distinguish oneself from the social and biological environment.

texts regarded as crucial. Here especially the implicit (sometimes trancelike) memorization is seen as fundamental for a proper immersing in religious patterns.

Sources of Authority

The investigation of memory and its disorders has been prominent since the writing of Greek philosophers and even before. Especially religious rules were treated with great care, and special instructions were established for proper memorizing. In the last two centuries, memory research flourished in numerous disciplines from neurology and psychiatry to the behavioral sciences. In 1885, Hermann Ebbinghaus wrote his well-cited book *Über das Gedächtnis* (On memory). In the same year, August Forel in Zurich published on “Memory and its abnormal states” (*Das Gedächtnis und seine Abnormitäten*). And from Ewald Hering’s short book “On memory as a general function of organized matter” (*Ueber das Gedächtnis als eine allgemeine Funktion der organisierten Materie*), published in 1870, a citation was already given above. Only a few years later, Pierre Janet wrote in France on “The mental state of hysterics” and emphasized that amnesia may be caused by adverse environmental stimulation. Similarly, in Prague, Anton Pick in 1886 wrote *Zur Pathologie des Gedächtnisses* (On the pathology of memory), and Theodore Ribot published in 1881 “*Les maladies de la mémoire*” (The disturbances of memory). Charcot and, even more so, his pupil Sigmund Freud provoked many debates by emphasizing the importance of the unconsciousness and of implicit memories. Some Russian scientists such as Korsakoff and von Bechterew established relations between brain damage and amnesia while others, in particular Ivan Pavlov established classical conditioning. The behaviorists followed in North America with rules for operant conditioning, with Burns F. Skinner becoming the most prominent among them. Much of the last half of the last century was then devoted to finding interactions between

brain and memory, starting in 1957 with the publication of William Beecher Scoville and Brenda Milner on the case H.M. H.M. received (already in 1953) a bilateral resection of his medial temporal lobes and became severely (anterogradely) amnesic from this time onward. Nowadays, names such as that of Endel Tulving from Toronto University are most well known. Tulving wrote in 1983 a most influential book entitled “Elements of episodic memory.” Later, he engaged himself in functional imaging studies on memory, a subject which thereafter became the topic of numerous other investigations. Other researchers attempted to establish relations between brain changes after stress-induced autobiographic amnesias.

Ethical Principles

As far as memory research is based on human beings and in particular on patients, the ethical principles of all medical disciplines apply (Declaration of Helsinki, 1971).

Key Values

Insofar as memory research is a clinical discipline, it focuses on methods and techniques intended to help patients to improve their memory or to prevent its deterioration.

Conceptualization

Human Being

Most, but not all, memory scientists see episodic-autobiographical memory as a unique capacity of human beings, while they consider all other forms of memory as shared with non-human beings.

Life and Death

There is at best an indirect relation insofar as cultural memory is considered to last over generations. Similarly, facts and traditions are transferred via memory over generations.

Reality

Memory, in particular autobiographical memory, is considered a dynamic process, which is dependent on numerous concomitant variables (mood, attention, experience, etc.) and therefore may lack all features of reality. In its more extreme variations, false memories or memory distortions may occur which lack a background of reality.

Knowledge

In modern memory research, there is a distinction between remembering and knowing. Knowledge is considered to deal with facts (*knowledge system or semantic memory*), remembering with autobiographical events.

Truth

As episodic memory is considered to be dynamic, it may vary on a gradient of truthfulness.

Perception

Memory depends on the perception of information. Perception itself is seen as the subjective conceptualization of sensations.

Time

Memory is embedded in time and changes with time. The dimension of time is fundamental to memory, though time is not chronometric but subjective with respect to memory. For example, in older age, subjective time may shrink.

Consciousness

The various memory systems rely on different degrees of consciousness with procedural memory being least dependent on consciousness and episodic-autobiographic memory most.

Relevant Themes

There are two critical issues, first the subjectivity of memories which is at present also noted in history and, secondly, the possibility of indoctrination via various forms of information transfer, for example, via subliminally presented messages.

Memory, Types of

Eichenbaum Howard
Center for Brain and Memory, Boston
University, Boston, MA, USA

Long-term memory is the permanent storehouse of memory that can be recovered by demand for remembering. There are several different types of long term-memory, including episodic memory and semantic memory, habits and emotional memories, and more. *Short-term memory* takes care of the information that is held internally for a brief period without thought or rehearsal. The size of short-term memory differs depending on the type of information and how memory is

tested. *Semantic memory* organizes knowledge abstracted from many experiences with overlapping stimuli and events, free of the sequences of events that compose individual experiences. *Working memory* refers to the information that can be held in mind actively and manipulated for an indefinite period. *Declarative memory* is defined in terms of our ability to bring what has been learned to consciousness. Conversely, nondeclarative memory is defined as learning that occurs and can be expressed without conscious awareness of specific learning events. *Nondeclarative (implicit) memories* are memories that are retrieved in ways other than conscious recollection, such as memories for reflexes or automatic abilities. It is the type of memory that results from unconscious learning and can be expressed unconsciously, including procedural learning and the acquisition of attachments or aversions to otherwise neutral stimuli. *Episodic memory* comprises memories of specific events in which one participated; they are organized as sequences of events that compose particular experiences. *Procedural memory* takes care of the habits formed as a result of classical or instrumental conditioning; it can occur and be expressed in terms of behavioral performance in the absence of conscious recollection of the learning experience.

[Jewish](#); [Messianism](#)

Messiah

From the Hebrew *mashiach* (“anointed”). Developed from the words of the biblical prophets, messianism expresses a popular hope for the liberation of the people, the return from exile, and an era of peace. In his classic essay on *The Messianic Idea In Judaism* (1959), Gershom Scholem emphasized the catastrophic visions of doom preceding the coming of the Messiah which are present in much Jewish messianic speculation. The actual word Messiah in the sense of an ideal future King does not appear in the Hebrew Bible, although the germ of the idea is certainly there. Jewish messianism has developed through movements which have followed charismatic individuals even more than through literary speculations. The Dead Sea Scrolls present a picture of two Messiahs at the end of days, the future King and the future Priest. The recently discovered ancient inscription known as the “Gabriel Revelation” presents a notion of catastrophic messianism, a war leader who will be

killed, a messiah of suffering and death from the tribe of Ephraim. Messianism played a part in the Jewish revolt against Rome of 66–70 CE, a war in which there were rival leaders from different Jewish sects. A key figure in the history of Jewish messianism is Shimon Bar Kokhba, a rebel leader who led troops against the Romans (132–135 CE). Rabbi Akiva is said to have accepted him as the Messiah. The total defeat of Bar Kokhba’s army led to fierce Roman persecutions and an immediate end to messianic hopes as expressed in rabbinic thought, although such hope remained an important part of the daily worship. The central prayer known as the *Amidah*, a Jewish prayer recited thrice daily consisting of nineteen benedictions, contains a prayer for redemption, one for the ingathering of the exiles, and one for the restoration of David’s kingdom, “the blossoming of the light of salvation.” The Babylonian Talmud (edited 500 - 600) has one long speculative passage about the Messiah (*Sanhedrin* 97a - 99a). It advises against trying to calculate when he will come, since God will only send the Messiah to a suitably repentant and worthy generation which is strict about keeping the Sabbath. The Talmud teaches that the advent of the Messiah will be preceded by the return of the prophet Elijah, and that the Messiah will be a direct descendant of King David. In medieval Jewish thought, the philosophers Nachmanides and Maimonides disagreed about messianism, with the former arguing that it was not central to Jewish thought and the latter making the coming of the Messiah a principle of the faith. Messianic debate surfaced more recently with movements who saw the Messiah more as a spiritual leader than a war leader- those who followed Shabbetai Zevi in the 1660 s and Rabbi Menachem Mendel Schneerson, leader of Chabad-Lubavitch in the 1990s. Chabad-Lubavitch began 250 years ago, but today’s worldwide movement began in the 1940s. Other modernists have promoted messianism without the personal messiah. In the first half of the twentieth century, some saw socialism as a secularized form of Jewish messianism. All these spiritual and secular examples show the power of popular thinking to outrun the theorists

and reshape the doctrine to fit a new age or a new leader. Although the coming of the Messiah remains a popular Jewish belief, there are those who believe redemption is at hand, and others who feel that the real practical application is an optimistic outlook for the world's future. The first group shares with science the goal of saving humanity from impending catastrophe, while the second group would accept the notion of scientific progress. However, messianism differs from a scientific approach in being ever changing and rooted in popular culture.

Description

Messianic Judaism is the religion of Jewish people who believe in Jesus (Yeshua) as the promised Messiah. It is a Jewish form of Christianity and a Christian form of Judaism, challenging the boundaries and beliefs of both (Boyarin 2004). The Messianic Jewish Movement refers to the contemporary movement, a renewed expression of the Jewish Christianity of the early church. Messianic Jews construct a new social and religious identity that they express communally in Messianic Jewish Congregations and Synagogues, and in their individual beliefs and practices. Since the early 1970s, significant numbers of Jewish people now believe in Jesus and identify as Messianic Jews. Their beliefs and practices raise important questions and challenge traditional understandings of Judaism and Christianity (Cohn-Sherbok 2000).

There are some 150,000 Messianic Jews worldwide, according to conservative estimates.

More than 100,000 are in the USA, approximately 12,000 in Israel, the remainder being found throughout the 13.4 million world Jewish population (2010, North American Jewish Databank). There are over 200 Messianic groups in the USA, 120 in Israel, and many others around the world (Kjær-Hansen and Skjøtt 1999). While they are not uniform in their beliefs and expression, the majority adhere to orthodox Christian beliefs on the uniqueness and deity of Christ, the Trinity, and the authority of scripture. They express these beliefs in a Jewish cultural and religious context while affirming the continuing election of Israel (the Jewish people) with which they identify.

To varying degrees, Messianic Jews observe the Sabbath, keep the kosher food laws, circumcise their sons, and celebrate the Jewish festivals. They celebrate Passover showing how Yeshua came as the Passover Lamb, and practice baptism, linking it to the Jewish *mikveh*. They worship with their own liturgies, based on the Synagogue service, reading from the Torah and the New Testament. Their hermeneutic of scripture repudiates the tradition of Christian Anti-Judaism that “the Jews killed Christ” and the metanarrative of supersessionism that the Church replaces Israel as the “new Israel.” They argue for continued Torah observance, identifying themselves as Jewish members of the Church, and as a believing “remnant” in the midst of Israel. Their eschatology is generally, but not entirely, Premillennial, seeing the return of the Jewish people to the Land of Israel as a fulfillment of prophecy (Cohn-Sherbok 2001).

Self-identification

Science

Messianic Judaism does not identify itself directly as a science. Messianic Jewish theology sees itself as a scientific field of enquiry concerning God, Torah and Israel. It is based on the twin epistemic foundations of the uniqueness of Yeshua as divine-human Messiah, and the ongoing election of Israel (the Jewish people).

Religion

Messianic Judaism identifies as a religious and cultural identity that situates itself within the primary social space of Jewish life and peoplehood.

Characteristics

Messianic Judaism is distinctive among Judaism and Christianity as an inseparable part of both, the “missing link” between the two traditions, that combines Christian affirmation of the uniqueness of the Messiah Yeshua (Jesus) as divinely incarnate Son of God with God’s ongoing election of Israel (the Jewish people).

Relevance to Science and Religion

Messianic Judaism is relevant to and interested in questions of cosmology (creation, evolution), psychology (free will, determinism), social psychology (social identity theory), social anthropology (anthropology of religion, conversion.), ethics (sanctity of life, personal and social morality), political science (peacemaking and conflict resolution in the Israeli-Palestinian conflict), theology.

Sources of Authority

The primary sources of authority are the Scriptures of the Old and New Testament, interpreted through Jewish and Christian history and religious tradition. Jewish tradition (Mishnah, Talmud, Midrashim, Codes, Responsa, Contemporary Jewish thought) strongly influences Messianic Jewish teaching and practice. Messianic Judaism, emerging from the Hebrew Christianity, was took birth in nineteenth-century Evangelical Protestantism (Kjær-Hansen 1995) but also relates to Orthodox and Roman Catholic traditions. The writings and work of nineteenth and early twentieth-century leaders of Hebrew Christianity (e.g., Joseph Rabinowitz, Sir Leon Levison, Hugh Schonfield) offer guidance to the

Movement. Within the different streams of the movement, the contemporary leaders (Daniel Juster, Mark Kinzer, David Stern) have varying levels of authority (Juster 1986; Kinzer 2005; Stern 1988). Harvey's survey provides a generally accepted statement of key theological issues and identifies 8 theological streams within the movement (Harvey 2009).

Ethical Principles

The Judaeo-Christian tradition, encourages love for God and neighbor, in the context of the transformation of the values and practice of the Torah through the death and resurrection of Yeshua (Jesus), the Messiah. These principles include justice, equality before the law, loving-kindness, social welfare, and the ideals of peace and political freedom.

Key Values

Messianic Jews focus on Torah as the guide for life, as exemplified by the life, teaching and ministry of Yeshua (Jesus). Respect for God, humanity, and practical holiness (*kedushah*) in everyday life.

Conceptualization

Nature/World

The world is created by God and reflects God's beauty, order, and creativity. It is marred by the effects of humanity's sin, but through the election of Israel to be God's people in God's land, and the atoning and salvific life and ministry of Yeshua, the nations will be engrafted into a renewed Israel, and the creation will be renewed and restored.

Human Being

All humanity is created in the image of God but is marred by the effects of the fall. Israel is elected to be a means of blessing to the nations and humanity will be redeemed through the death and resurrection of the Messiah and restored to

enjoy relationship with God in restored humanity. The individual is to be understood aspectively as comprising body, soul, and spirit, and corporately as belonging to family, people, and ethnicity (social identity). The dyadic relationship of Israel and the nations is an ecclesiological given that proleptically anticipates an eschatological unity within the differentiated order of a new humanity (Soulen 1996).

Life and Death

Life is the gift of God, beginning physically at the moment of conception. Physical death is the forerunner to judgment, resurrection, and a corporate eternal state.

Reality

Messianic Jews are influenced by Michael Polyani's *Critical Realism*. The writings of Thomas Torrance, Michael, Edith Wyschogrod, and Emmanuel Levinas influence their ontology.

Knowledge

Special revelation of God is through the Scriptures, the Incarnation of Yeshua, and the proclamation and practice of the community of the faithful. General revelation is through sense-experience of the everyday world, moral consciousness, and the order of creation.

Truth

Truth is both propositionally revealed and personally appropriated, mediated through reason, tradition (both Jewish and Christian), and the Scriptures.

Perception

Messianic Jews follow externalism and critical realism, but the term is not defined explicitly within this tradition.

Time

Messianic Jews see time as both linear (but not evolutionary positivist), and also cyclical. There are different understandings on the qualitative nature of the boundary between the "now" of the present age (*olam Hazzeh*) and the "not yet" of the world to come (*olam haba'ah*) which result

in several different eschatological systems of Amillennialism, Dispensationalist, and Historic Pre-Millennialism.

Consciousness

Messianic Jews see individual consciousness as a property of the human mind/soul, which continues ends in death and is restored in resurrection. Religious experience may be the result of altered states of consciousness.

Rationality/Reason

The exercise of reason and the systems of rationality found in different societies reflect the created order and the rational character of the Creator God. Human reason follows principles of argument and logic, but rationality in complex social systems reflects cultural and worldview assumptions that are often not made explicit. Messianic Jews situate themselves within the Christian and Jewish worldviews, where “rational arguments” on topics of controversy are problematic.

Mystery

Mystery is truth beyond the comprehension of human reason unless revealed by illumination of the consciousness through the agency of the Holy Spirit. The existence of God, the Messiahship of Yeshua, the realities of sin, judgment, and eternal life are all mysteries that require revelation.

Relevant Themes

1. Cosmology – creation and scientific accounts of the origin of the world.
2. Compatibilism, Freedom and Determinism – human free will and the foreknowledge of God.
3. The being and activity of God in and beyond time and space – His triune nature and involvement in the created order. The divine-human nature of Yeshua (Jesus) – How can this be expressed?
4. Life after death – What is the nature of resurrection, both personal and corporate?
5. Social identity and ethnicity – who is Israel?

Meta-heuristics

M. Teresa Ortuño

Department of Statistics and Operational
Research I, Universidad Complutense de Madrid,
Madrid, Spain

Meta-heuristics is the most recent development in approximate search methods for solving complex optimization problems that arise in business, commerce, engineering, industry, and many other areas. A meta-heuristic guides a subordinate heuristic using concepts derived from artificial intelligence, biological, mathematical, natural, and physical sciences to improve their performance. Notable examples of meta-heuristics include genetic/evolutionary algorithms, Tabu search, simulated annealing, variable neighborhood search, GRASP, and ant colony optimization, among many others (see *Meta-heuristics: theory and applications*, I. H. Osman and J. P. Kelly ed. Kluwer Academic Publishers, 1996).

Metaphysical Theology

Metaphysics

Carl Raschke

Department of Religious Studies, University
of Denver, Denver, CO, USA

The science of “first principles” or “first causes” as laid out by Aristotle in his book *Metaphysics*.

Much of the development of modern physics has proceeded from an empirical refinement through mathematical modeling or empirical investigation of theoretical propositions that can be defined as “metaphysical.” Aristotle regarded metaphysics in much the same way as modern philosophy of science regards the practice of science. The philosophy of science studies and analyzes the theoretical premises and procedures as well as the general ground plan of knowledge that enter into the pursuit of science as an empirical discipline. Today metaphysics is a separate branch of philosophy that no longer enjoys the prestige it possessed in its heyday up until the early nineteenth century. The philosopher Immanuel Kant redefined metaphysics as an inquiry into the foundations of how knowledge as a whole is gained, making it an appendage of *epistemology*, the theory of knowledge. In this view, the “first principles” of philosophy can no longer count as basic elements of the universe itself, but as rules or assumptions for how we can come to know the universe in a reliable fashion.

Metaphysics, Darwinian

Momme von Sydow

Department of Psychology, Universität
Heidelberg, Heidelberg, Germany

Related Terms

[Darwinism](#); [Universal](#)

Description

“Darwinian metaphysics” may be seen as a compound of two antonyms, since Darwinism

has often been treated as a scientific theory opposing religious and philosophical kinds of metaphysics. Correspondingly, the use of such term may appear provocative, almost as if one were using “Darwinian religion” to designate a general Darwinian approach. The approach and the term itself, therefore, are bound to elicit criticism from positivistic as well as metaphysical positions. Nevertheless, “Darwinian metaphysics” appears to be a suitable term for all historic or recent approaches claiming that Darwinian processes essentially offer a universal account of biology, culture, and our very being. Although Charles Darwin did indeed mainly concentrate on biology, he speculated that his theory would at least “give zest [...] to whole metaphysics” (Notebook B, p. 228). Before we discuss Darwinian metaphysics in the narrow sense, based on a radicalization of Darwinism, we will briefly discuss the proposition that in fact several quite different approaches may be interpreted as Darwinian metaphysics.

Darwinian metaphysics in a *broad sense* is difficult to characterize, since throughout intellectual history “Darwinism” has been presented in different forms and has been used to build syntheses with many other ideas. For instance, Darwinism, even if defined as a biological theory of natural selection, has had an influence on quite different kinds of social Darwinism, from *laissez-faire* capitalism to racism to anarchism. Likewise, historians have linked Darwinism to many philosophical systems – for instance, to that of Herbert Spencer, Ernst Haeckel, William James, and Charles Sanders Peirce. Furthermore, although Darwinism sometimes seems to be linked to progress (at least in the sense of adaptation), Darwinism allows for *local* adaptation only and hence is generally considered to preclude the possibility of genuine progress (see, e.g., Gould 2002) – not least because the process underlying evolution is interpreted to remain essentially static (see, e.g., von Sydow 2012). Likewise, since apparent purpose seems actually to be based on a blind mechanism, Darwinism has sometimes been interpreted as a nihilist doctrine. Darwinism, with the central concept of struggle for life, particularly among

conspecifics, appears to emphasize conflict over cooperation. Moreover, Darwinism at least probabilistically seems to have been correlated with materialism and atheism. Yet one should also note that from the very formulation of Darwinism there have been attempts to interpret natural selection in the opposite direction, linking natural selection to God’s invisible hand. Historically, the relationship between science and religion has been more volatile and intricate than today’s actual conflict between a radicalized Darwinism and a radicalized religious fundamentalism would suggest. Darwin himself not only studied theology at the University of Cambridge, but he in fact seems to have aimed at retaining some aspects of William Paley’s natural theology in his elaboration of the theory of natural selection (even though the theory indeed contributed later both to Darwin’s own increasing agnosticism and a quick decline in the estimation of Paleyan natural theology; see von Sydow 2005).

It is important to distinguish Darwinism from evolutionary theory as such (evolution was advocated in different schools in France and Germany before the publication of *The Origin of Species*). Furthermore, some philosophers (such as Teilhard de Chardin, Henri Bergson, and Alfred North Whitehead) made interesting proposals for a “metaphysics of evolution” that must be seen in contrast to any “Darwinian metaphysics.” On the whole, the relevance of biological Darwinism to ethical or religious issues is highly controversial. There was reaction against the influence of Darwin in the fields of philosophy as well as theology, as well as objection on the part of several authors to the asserted direct relevance of biological theories to ethics (e.g., G. E. Moore) or revealed religion (e.g., K. Barth). Whether one can postulate an epistemic autonomy of these disciplines, however, seems to depend on one’s preexisting logical, epistemic, ontological positions, and also on the details of one’s biological account. Correspondingly, different sub-paradigms of Darwinism displayed different views on the autonomy of culture or ethics. Theories that can be characterized (at least partly) as Darwinian, such as Darwin’s first formulation of Darwinism, Weismann’s neo-Darwinism, the

early evolutionary synthesis, the late evolutionary synthesis, gene-Darwinian sociobiology, and multilevel-Darwinism, held different positions with respect to reductionism and the autonomy of sociology and ethics (see, e.g., von Sydow 2012). Overall, the heterogeneity of thought on Darwinian metaphysics has two main reasons: first, the variation of underlying biological theories and second, the fact that “auxiliary hypotheses” needed to link Darwinism to metaphysics sprang from various traditions.

Darwinian metaphysics in a more *narrow sense* is based on a “purer” Darwinism and (less pluralistic) understanding of the theory. K. R. Popper, D. Campbell, R. Dawkins, D. C. Dennett, and (arguably) D. Hull may be cited as main proponents of this Darwinian metaphysics – of which two types need to be distinguished: gene-Darwinism and (universal) process-Darwinism.

The first type, *gene-Darwinism*, is a radical interpretation of Darwinism that became popular in the 1970s. Its basic ideas have been popularized, particularly by R. Dawkins and G. C. Williams. Pure gene-Darwinism reduces living entities and processes in the biological and social worlds to single selfish genes in Darwinian processes struggling for survival (for a critical survey, see von Sydow 2012). Phenotypes as well as products of organisms, such as beavers’ dams or human habitation structures (so-called extended phenotypes) are interpreted as mere ephemeral vehicles of potentially immortal selfish genes (Hull and colleagues deviates on the issue of vehicles and sees them as interactors, Hull et al. 2001). In the words of R. Dawkins, just as “Chicago gangsters, our genes have survived, in some cases for millions of years, in a highly competitive world. This entitles us to expect certain qualities in our genes. I shall argue that a predominant quality to be expected in a successful gene is ruthless selfishness. This gene selfishness will usually give rise to selfishness in individual behaviour.” (*The Selfish Gene*, 1976, p. 2; cf. Dawkins 1983). One reason to regard gene-Darwinism as a purification or radicalization of Darwinism is that one defining aspect of traditional Darwinism (at least Darwin’s

Darwinism) is a reductionist stance in the units of selection debate by a primary focus on individuals (which, according to Gould 2002, is one of three defining aspects of Darwinism). The focus on selfish genes (gene-reductionism) thus radicalizes the reductive tendency inherent in traditional Darwinism as well. Moreover, like Darwin’s Darwinism has been contrasted to earlier romantic accounts, which stressed the “evolution” or “unfolding” of nature and the role of form and structure, gene-Darwinism in a second sense radicalizes Darwinism in this respect as well, by degrading phenotypes to puppets or mere vehicles of genes (germ-line reductionism). Finally, whereas paradigms that were perceived as Darwinian (such as Darwin’s Darwinism and the evolutionary synthesis in its later phase) remained to advocate a limited process-pluralism, gene-Darwinism reduces all evolutionary processes to the only truly Darwinian process of natural selection (process reductionism). For example, sexual selection from the perspective of single genes cannot be seen as a mechanism in its own right (referring to a special kind of what one may call auto-selection); rather, the process becomes identical to natural selection (both equally referring to hetero-selection). It may even be argued that the entity “gene” – or, more abstractly, the entity of an atomic “replicator” (see Dawkins 1983) – directly corresponds to or is equivalent to a Darwinian process of replication, blind variation, and external selection (von Sydow 2012). However that may be, according to gene-Darwinism there is essentially only one entity – the selfish gene – and only one evolutionary process – a Darwinian process. God, according to universal Darwinism at best is a blind watchmaker. The question of whether Dawkins and Dennett’s prominent critiques of religious thought are directly linked to this position may remain open (*The God Delusion*, 2006; *Breaking the Spell*, 2006). Nevertheless, if one advocates a pure gene-Darwinian position and takes up the sociobiological battle cry to “biologize” social sciences and ethics (E. O. Wilson), one ought not be surprised when several gene-Darwinian authors (despite R. Dawkins’ more cautious

Metaphysics, Darwinian, Table 1 Process-Darwinism and specific Darwinian processes in selected disciplines

Discipline	Object of evolution	Darwinian processes	Authors
Biology	Genes	Blind mutation and natural selection	G. C. Williams, R. Dawkins
Psychology	Operants, acts, associations	Trial and error	B. F. Skinner, D. T. Campbell
Philosophy of science	Theories	Conjectures and refutations	K. R. Popper, S. Tolmin
Economics	Firms, products, routines	Innovation and market selection	M. Friedman

position on ethics) consider maximization of gene-replication as the only ultimate biological categorical “imperative.”

The second type of Darwinian metaphysics is *process-Darwinism*, with roots going back to A. Weismann and C. S. Peirce. Whereas at first Weismann advocated the omnipotence (“Allmacht”) of the one basic process of natural selection, later he postulated several levels of what are now referred to as Darwinian processes. During the course of the twentieth century, the main contributions to process-Darwinism were made by R. Campbell, D. C. Dennett, D. Hull, H. C. Plotkin, K. R. Popper, and R. Dawkins. Process-Darwinism need not be committed to gene-reductionism, and yet it retains as defining characteristic Darwinian process reductionism. Whereas gene-Darwinism allows for natural selection on the single level of selfish genes alone, process-Darwinism claims that these processes exist on several levels, and in fact constitute the only remaining processes of adaptation. D. Campbell (1960), in an early main contribution, advocated that Darwinian processes were the only processes of “knowledge acquisition.” Darwinian processes represented the algorithmic structure of natural selection (in a broad sense) as defined by the two-step process of blind-variation-and-selective-retention (Campbell 1960). The last of the two subprocesses may likewise be called “external selection” or “environmental selection,” since it generalizes natural selection (in the narrow sense). Finally, Darwinian processes are normally assumed to lead to a gradual evolution.

What are the main levels (or domains) in which a process-Darwinian account has been elaborated? Even within biology, the revived

multilevel approach in evolutionary biology, criticizing pure gene-Darwinism (Gould 2002; Wilson and Wilson 2007), assumes (at least in some of its proposals) the central role of Darwinian processes (for instance, on the level of species; cf. the work of M. T. Ghinselin and D. Hull). However this may be, the term “process-Darwinism” is preferably to be used in accounts where Darwinian processes have been advocated outside of evolutionary biology as well. Proposals have been discussed in a number of domains, from immunology, neurology, and language-development to its three main areas: philosophy of science, psychology of trial-and-error learning and creativity, and economics (see Table 1 for an overview).

First, falsificationism, founded by Sir K. R. Popper, had a strong impact in philosophy of science, but was first advocated without explicitly linking it to Darwinism. Popper’s original position is usually introduced based on an asymmetry between verification/confirmation and falsification – a theory taken as a universal statement can never be fully verified by observations but may be falsified by a single one. On this basis, Popper opposed any form of inductive confirmation and argued that scientific theories can be falsified only. Yet in his book, *Objective Knowledge – an Evolutionary Approach* (1972), Popper in fact closely linked his postulated theory of conjecture-and-refutations to Darwinian evolution. Correspondingly, for Popper the development of ideas was irrational and analogous to chance mutation. Likewise, R. Dawkins (1976; cf. 1983) advocated that ideas evolved by a Darwinian process. He coined the term “meme” as analogous to “gene” for atomic replicating and mutating elements of thought that

were the units of selection. Whereas Dawkins assumed a radically reductionist stance within biology, for the meme-level as a whole he appeared to advocate a degree of autonomy. Although the consistency of such a position has been criticized, nevertheless it represents an interesting attempt at reviving the idea of a cultural level, here by replacing with Darwinian processes such traditional notions as “logos,” “spirit,” or “Geist.”

Second, trial-and-error learning (or “operant conditioning”) has been central in psychology to the behaviorist concept of learning. Although one may interpret the rigid research program of behaviorism partly as a bulwark against biology, paradoxically B. Skinner actually postulated that he is introducing a Darwinian process at a second level. The analogy of trial-and-error learning with mutation and selection (or, more correctly, with blind-variation-and-selective-retention) has been explicitly elaborated (Campbell 1960; Hull et al. 2001). Likewise, psychological creativity has been interpreted as a Darwinian process (by D. Campbell and D. K. Simonton; cf. Campbell 1960 and Gabora 2005).

Finally, analogies between neoclassical economics and neo-Darwinian biology have been discussed. Some have treated Popper’s philosophy as founding a philosophy of radical capitalism (although in *The Open Society* he actually allowed for some degree of state intervention). Similarly, the work of M. Friedman, who backed the neoliberal policies of the last decades of the previous century, was partly inspired by Darwinian ideas. Moreover, several proposals in economics have been made that directly refer to the concept of universal Darwinism, where companies or routines have been interpreted as evolving by Darwinian processes, with innovations corresponding to mutations and given consumer preferences to the natural selection by the invisible hand of the market (confer, e.g., Hodgson 2002).

With respect to these Darwinian processes, it is debatable whether their postulated combination (in a process-Darwinian account) in fact yields – implications that are quite non-Darwinian (e.g., non-blind variation at some

level) and; also whether this leads to inconsistencies, thus transcending strict process-Darwinism (von Sydow 2012). Likewise, although process-Darwinism normally continues to stress competition (the struggle for life) over cooperation (both in biology and economics), it should be noted that process-Darwinism allows for the argument that our thoughts, ideas, and theories die instead of us (P. Munz), mitigating a nature red in tooth and claw. Finally, although advocates of process-Darwinism usually subscribe to a naturalistic research program, the emphasis on the algorithmic level of natural selection (cf. works of D. C. Dennett or P. Munch) may be interpreted to go beyond this commitment, basing the theory on a mathematical structure, a form or a principle, rather than on matter or observations.

Let us return, however, to the question of whether it is appropriate to treat these Darwinian theories as metaphysical systems. Depending on one’s understanding of metaphysics, such labeling may either be too high an honor for these sometimes philosophically naïve Darwinian theories – traditionally the highest discipline of philosophy – or else it is too severe a discredit to them to be assigned to a philosophical discipline that from a positivistic viewpoint concerns itself with “meaningless” questions. Many authors today, however, use the term “metaphysics” in a more liberal way, neither necessarily referring to an all-embracing philosophical system set up a priori by a single author, nor accusing metaphysics of being a vacuous system of tautological claims. The term “metaphysics” is not restricted to continental philosophy, but rather has come into use as well in what may still be broadly called “analytical philosophy.” Yet what would be an appropriate reply, if one nevertheless argued that these Darwinian theories were results of plain empirical induction, with no metaphysics involved?

First, historically, Darwin’s great synthesis was clearly not only a great *empirical* synthesis, but a *theoretical* one as well, formulated while ordering the evidence gathered during his journey with the HMS Beagle in the light of available theories of his day (being strongly influenced,

for instance, by Malthus, Paley, Lyell, Grant, etc.). Interestingly, these influences extended to theological approaches (Rev. Malthus and Rev. Paley). Darwin himself acknowledged the influence of William Paley's natural theology, and conceded that everyone with such metaphysical preconceptions would have exaggerated the belief in adaptation and "naturally extend[ed] too far the action of natural selection [...]" (Darwin, *Descent of Man* 1877; cf. von Sydow 2005, p. 154). This is the case, although Darwin's theory of natural selection seems to have dealt a death blow to natural theology as well as to Darwin's own belief. However, Darwin's Darwinism in its initial formulation was even by Darwin's own claims not based on "plain empirical induction" but rather was influenced by theoretical and even theological considerations. Even were this not so, one could still question a presupposed strictly rationalist understanding of metaphysics. Notably, today one hears the term "empirical metaphysics" as well.

Second, gene-Darwinism and process-Darwinism are not generally advocated in the context of a single specific discipline, but rather are universally advocated for all living entities. Attempts have been made to apply gene-Darwinism to "biologize" sociology and ethics. Process-Darwinism has developed for instance in biology, psychology, the history of ideas, and economics. Hence the term "universal Darwinism," introduced by Dawkins (1983), seems appropriate. If generality of the intended field of application is taken as a criterion for a theory's being termed a metaphysical approach, and if another criterion is the abstractness and simplicity of the basic explanatory concepts (for both types of Darwinian metaphysics: Darwinian processes), then we are clearly concerned with metaphysical systems.

Finally, and foremost, the claimed generality of Darwinian processes is to be classified as a metaphysical approach even if one adopts a rationalist understanding of metaphysics based on self-evident principles or a priori truth. In fact, major authors of Darwinian metaphysics (Popper, Campbell, Dawkins, and Dennett) present their approach based on principles or

theoretical arguments, which in a way constitutes a "fundamentalist" position. Paradoxically, Darwinian metaphysics, often depicted as empirical generalization or a positivist "success story," actually seems to revive the rationalist project of an ultimate theoretical justification of a metaphysical position based on first principles. It may suffice here simply to mention Popper and Dawkins. Popper did not argue inductively in favor of a high generality of Darwinian processes, but instead advocated their universality in principle. His argument is in fact based on logical considerations – the above-mentioned logical asymmetry of falsification and verification – and is linked to the fundamental problem of induction that is often attributed to the philosopher David Hume (see below). It is only on this basis that Popper could argue in such a general way that the "growth of our knowledge is the result of a process closely resembling what Darwin called 'natural selection'; that is, the natural selection of hypotheses: our knowledge consists, at every moment, of those surviving so far in their struggle for existence; a competitive struggle which eliminates those hypotheses which are unfit. [...] The theory of knowledge which I wish to propose is a largely Darwinian theory of the "growth of knowledge. From the amoeba to Einstein, the growth of knowledge is always the same [...]" (Popper 1972, p. 261). Dawkins as well seems to be committed to a rationalist foundation of universal Darwinism, making it a truly metaphysical account (1983). He claimed that Darwinism is not only empirically, but also theoretically "probably the only theory that *can* adequately account for phenomena that we associate with life" [italics added]. Other explanations were "in principle incapable of [...] explaining the evolution of organized, adaptive complexity" (pp. 403, 404). Dawkins has argued against any form of instructivism: "Even if acquired characters are inherited on some planet, evolution there will still rely on a Darwinian guide for its adaptive direction" (p. 409).

In this last section, two theoretical reasons will briefly be considered for assuming a Darwinian metaphysics. First, a main "metaphysical" argument favoring Darwinian metaphysics is linked

to the fundamental problem of induction often attributed to David Hume in the eighteenth century. This problem may have had an even longer history: For in scholastic philosophy, first formulations of the problem were paradoxically used to support religious or rationalist positions against empirical ones. Hume, however, with the goal of justifying empirical induction, showed that one cannot “prove that those instances, of which we have had no experience, resemble those, of which we have had experience” (*A Treatise of Human Nature*, 1739/1740, Book I, Part III, sec. VI). Nature may change its course and our inductions rendered false. This in fact implies that all our knowledge, including such a simple and apparently well supported claim as “the sun will rise tomorrow,” may be fallacious. Popper concluded that no confirmation of a theory will ever make a theory “truer” or only more “probable” than a less supported alternative (provided the alternative has not already been falsified). Accordingly, there are no true or probable theories – only theories that have or have not been falsified. Such a “negative solution” to the problem of induction in Popper’s logic of discovery asserts that scientists in fact make blind conjectures and that they should rather aim solely at refutations (falsifications). This, moreover, supports a universal justification for Darwinian processes of blind conjectures and environmental refutations.

The fundamental problem of induction is a highly intricate and hotly disputed issue in philosophy and cannot be treated in any further detail here. Yet it must be noted that Popper’s position is highly controversial in philosophy of science (starting with early criticism by W. V. O. Quine, H. Putnam, and I. Lakatos). Several authors, for instance, have argued that the postulated asymmetry of confirmation and disconfirmation does not hold with regard to complex or compound theories (where it is not clear which aspect of a theory is to be falsified), nor with respect to probabilistic relationships (as they cannot be falsified by single disconfirmations). Moreover, one may object to the link between the problem of induction and falsificationism: Although plain falsification of a formerly

“valid” rule deductively proves that the rule does not hold overall, a falsification applied to the past rule does not logically prove that the rule may not hold in the future. If one assumes that prediction is essential to organisms as well as to scientists, the problem of induction seems to apply equally to falsifications. Although the problem of induction remains fundamental, it may therefore be argued that this problem does not necessary favor a falsificationist approach over a confirmatory one. Furthermore, in recent years there has been a revival of Bayesian approaches, both in philosophy of science (e.g., C. Howson and P. Urbach) and in psychology (e.g., M. Oaksford and N. Chater); that is, it is argued that people, when testing logical hypotheses, search for data in a rational, informed, and more active way than would follow on the basis of Darwinian processes alone.

The second way, Darwinian metaphysics may have gained plausibility (at least in popular writings) may be linked to the unclear meaning of the phrase “survival of the fittest.” Darwin borrowed this expression from H. Spencer in 1869 as a synonym for “natural selection.” Yet, although it appears on the surface to be both testable and plausible, it may be also be interpreted as a tautology: That is, if fitness is interpreted in terms of survival, this results in the phrase of the “survival of the survivor.” More refined definitions are of course possible and have been proposed. For instance, “fitness” is often defined in terms of reproduction, but this does not in fact resolve the problem, since one would then be obliged to measure the term “survival” in terms of reproduction as well (in order to avoid a formulation that is plainly false). Similarly, one may consider a probabilistic formulation of fitness. Once again one would need to look at both sides of the phrase which once again would produce a truism: “those organisms probably survive which probably survive.” The possible problems arising from these “improved” reformulations may in fact question whether “survival of the fittest” is always being used in testable way. It is of course beyond reasonable doubt that evolution and the Darwinian evolutionary theory provide a plethora of testable and

very well tested theories. Nonetheless, it seems plausible that at times it is only more specific theories that are tested, leaving the “survival of the fittest” as an explanatory framework rather than as a testable theory. Nonetheless, it is not claimed here that “survival of the fittest” is always and necessarily used in a tautological way. Actually, there seem to be ways to define “survival of the fittest” falsifiably, but the tautological meaning, broadly applied, may well have played a role in immunising Darwinism and popular versions of universal Darwinism in particular (von Sydow 2012). As such this seems connected to the observation of biologists Gould and Lewontin that adaptive explanations are sometimes be nothing but ad hoc “just-so-stories.” Interestingly, moreover, it was Popper, among others, who pointed out that a “considerable part of Darwinism is not of the nature of an empirical theory, but is a logical truism” (1972, p. 69). Even though he modified his views on this issue later, this is particularly noteworthy, since he modeled his own approach on an analogy to Darwinism.

Outlined here are only a few possible discussions of the metaphysical arguments, with no claim at providing a definitive result. Significantly, the apparently positivist approach of a universal Darwinism appears to revive the philosophical disputes on metaphysical issues in a way that seems relevant to several scientific domains. Other interesting topics in Darwinian metaphysics (particularly for process-Darwinism) concern conceptual and empirical issues. Are mutations, trials, conjectures, innovations, and new ideas actually strictly blind? Is selection strictly external or environmental? Is variation supplemented by synthesis? Could combinations of Darwinian processes result in irreducibly non-Darwinian processes? Is there top-down causation of emerging entities and processes? These are controversial matters, partly raised concurrently in varying domains of process-Darwinism (e.g., Gabora 2005; Hodgson 2002; von Sydow 2012). This, however, brings us back to the earlier point made about tautological definitions. That is, it may depend on our definition whether we define Darwinian processes so widely that Darwinian metaphysics

become almost a truism, or whether we define them as rigidly as possible, with the result that they become false almost by definition. Within metaphysics, one generally preaches to the converted if one argues that – besides factual issues – definitional issues often decide over the truth or falsity of theories or even of metaphysical systems of theories. However, in Darwinian metaphysics it seems clear that a greater awareness of definitional practices and implications may be helpful.

Description

Methodology in psychology refers to procedures researchers use to answer specific questions. There is no single methodology that all psychologists use. Instead, different schools and disciplines within psychology employ specific methods, some unique to a given discipline, while others are common across disciplines (Todd et al. 2004). For instance, for many psychologists, methodology refers to procedures and designs that permit the identification of causal relationships between independently defined variables. An explicit method by which such relationships are identified assures that other researchers can produce

identical results using the same procedures. This produces the single most important criterion identifying a discipline as a science, the public replication of causal claims. Thus, the major criteria that methodology addresses are repeatable findings by independent investigators in support of nomothetic laws or explanatory principles that apply to all instances of the same type of phenomena (Kuhn 1962; Motterling 1999). These laws are considered the scientific explanation of the phenomena studied. These assumptions and procedures are shared by psychologists who consider psychology to be a natural science (Roth 1987).

However, psychology is a many-faceted discipline, and not all psychologists consider it to have achieved the status of a natural science, and others would deny that it ought to strive to be one. Thus, there are a variety of methodologies used in psychology, each with its benefits and costs and all implying a particular set of assumptions regarding the nature of psychology. The assumption that psychology is or ought to be a natural science can be contrasted with the assumption that psychology is a human science (Denizen and Lincoln 2002; Wallerstein 1992). Those who identify psychology as a human science employ methods that are linked to the assumption that human beings are unique and have characteristics that are not reducible to the parameters of natural science. These psychologists have devised a variety of methodologies that do not simply focus upon causal relationships. Thus, contemporary psychology is characterized by methodological pluralism. No single method can be adopted uncritically; rather, methods are linked to assumptions investigators make about the nature of psychology and to the kind of questions they seek to answer. For instance, to ask “Under what conditions do dreams occur?” requires a methodology to identify causation, while to ask “What do dreams mean?” requires hermeneutical methods that assume dreams are meaningful phenomena capable of interpretation. This is one cleavage that divides methodology in psychology. Methods designed to identify causal relationships of necessity are quantitative as opposed to qualitative methods. Thus, we begin our discussion of methodology in psychology with quantitative methods.

Experimental and Quasi-Experimental Methodologies

Insofar as psychology is considered to be a natural science, the gold standard for methodology is the experiment. However, often experimental designs cannot be used, especially with respect to random assignment of participants to experimental and comparison groups. When this is the case, quasi-experimental methods are employed (Lee 2000; Todd et al. 2004).

Experimental Methods. For those committed to a natural science frame for psychology, the essential methodology is the experiment. It can be used most effectively for the study of basic psychological process such as memory or for identifying neurophysiological correlates of psychological phenomena. While random assignment is essential for a true experiment, quasi-experimental designs allow for meaningful comparisons between convenience samples who happen to differ on some significant variable.

Both experimental and quasi-experimental methods follow a similar pattern. The sequence is to (1) set the stage for the experiment, (2) create or identify one or more independent variables, (3) identify or create and measure one or more dependent variables, (4) conduct the experiment, and (5) engage in necessary postexperiment follow-up procedures, including debriefing if deceptions have been involved (Roth 1987; Todd et al. 2004). Experimental designs are heavily linked to measurement, or the capacity to assign numbers to psychological variables that have been operationally defined. Likewise, analysis of experimental data is heavily linked to various statistical procedures in order to test for significance of effects. While experimental and quasi-experimental designs are the methods that most clearly link psychology and the natural sciences, others methods are employed by those who assume psychology to be a uniquely human science.

Other Methods

The Use of Personal Documents, Questionnaires, and Diaries. Here, individuals are simply asked to report upon or keep records of specified experiences of interest to the researchers. Such reports can be analyzed by a variety of qualitative and

quantitative procedures and can yield a rich descriptive base to the report of lived experience as well as the ability to correlate these reports with a variety of variables of interest to the psychologist. All these methods are valuable but are tainted with established recognitions of the biases and limits of what are essentially self-report data (Denizen and Lincoln 2002).

Survey research methods allow for much wider sampling of persons. Several widely established surveys poll persons in sequential time periods, often using questions that are repeated and can track changes over time. Surveys can be administered by mail, phone, Internet, or personal contact. Each has identified problems that must be balanced against the value of the data obtained. Survey data has the advantage of assessing large numbers of persons across many demographic variables such as age, sex, income, and geographical location.

Scales and Measurement. The relationship of methodology and measurement previously noted is manifest in the use of scales and measurement by psychologists. Psychologists are well versed in scale construction, a major means by which variables of interest to the psychologists are measured. Most scales are multidimensional, suggesting that any construct has more than one facet. Scales assure at least ordinal measurement which identifies variations in degree, but most psychologists treat their scales as interval measurement by simply having individuals answer items on a continuous point scale.

This allows the requirements of many advanced statistical techniques to be met. Scale and measurement allow for the use of sophisticated statistical techniques to quantify human traits, aptitudes, and beliefs. A major methodological technique is to correlate various independent defined measures to test specific theories. Scales also allow for quantitative description of various psychological variables of interest. For instance, personality theorists can specify and quantitatively identify various factors or traits that comprise personality. Scales and measurement allow for the interaction between qualitative and quantitative methods. For instance, any nominally identified variable such as sex can be transformed into a quantitative variable by the simple assignment of numerals 0, 1 for each sex.

Case study methods are favored by psychologists who seek ideothetic (also ideographic) or detailed understanding of a single unique event. Psychoanalytic and object relation theorists have created specific methods to uncover unconscious mental processes assumed within these theories to be determinants of human behavior. While rejected by many as not consistent with natural science, methods of free association, dream analysis, and study of transference allow for detailed descriptions of individual persons. While most represented by psychoanalytic and object relation theorists, the case study method is used in a variety of clinical and personality studies linked to other theoretical traditions (Wallerstein 1992). Case studies are also heavily enmeshed in psychohistorical studies where individuals are analyzed in terms of their influence in history. Historical events are unique in that they are nonrepeatable in their specifics, even if repeated in terms of their general type. Social psychology, when embedded in the real world and conceived over time intervals, merges with historical studies. Thus, like history, some psychology has both nomothetic (lawful regularities) and ideothetic (unique event) qualities. This requires that psychologist use methods specific to the nature of the questions they seek to answer.

“Ideothetic” rather than “ideographic” is the preferred term to identify unique events for which no covering laws apply as in nomothetic events. While nomothetic methodologies ignore the uniqueness of events, ideothetic studies highlight what is unique about any phenomena of study and are thus essentially $N = 1$ studies. Nomothetic methodologies are heavily linked to statistical methods for the analysis of data while ideothetic methodologies are linked more to hermeneutical methods of interpretation. However, the distinctions are not absolute. While nomothetic studies employ a wide variety of quantitative methods, qualitative studies provide a rich descriptive frame and focus upon the meaningfulness of behavior. Nominal units of analysis identified in qualitative studies can be quantitatively analyzed as well by simply assigning numbers (1, 2) to nominal categories. Thus, nominal identification as a qualitative method is also rendered a quantitative measure.

Likewise, no matter how sophisticated the experimental study, nor how complicated the statistical analysis for the data, in the end the investigator must tell us what the data means. Thus, quantitative studies have an inherent and essential qualitative component as well.

Closely related to the case study is what can be called confessional research methods. They are particularly common in drug investigations, especially the study of entheogens that were previously identified as psychedelic drugs. Here, investigators experiment upon themselves with drugs in order to document the experience (Shanon 2002). Once common in psychology, where the term “subject” actually meant the researcher served as his own subject, confessional research is once again influential in modern psychology. For some confessional researchers, the use of drugs allows them to experience psychotic states and thus to empathetically relate more effectively to patients, for others drugs trigger spiritual experiences and allow for more sophisticated research strategies designed to capture the nature and determinant of such experiences. Controversy surrounding confessional methods ranges from a concern with a loss of objectivity to one of the dangers of rampant apologetics linked to a sense of the ontological wonder of altered states elicited by chemicals.

Field research includes ethnographic and participant observation. Often identified as field research, the crucial distinction is that the research occurs in a natural as opposed to laboratory setting. The researcher documents activities as he or she participates in varying degrees with the activities being studied. Ethnographers tend to emphasize “thick” descriptions and to capture an epic (insider point of view) rather than an etic (outsider’s point of view). Etic explanations move toward homothetic or covering law explanations; emic descriptions parallel case studies and ideothetic explanations but now of entire cultures rather than a single individual. Field research often includes unobtrusive measures, or the use of naturally occurring indicators available to the researcher (Denizen and Lincoln 2002; Lee 2000). For instance, wear patterns on a rug indicate traffic pattern flow.

Phenomenological methods allow participants to describe what appears to consciousness while

bracketing any claims to the reality status of such appearances. They are thus noncausal methods. These methods are particularly useful in allowing psychologists to understand how the world is experienced differently by people, ranging from those deemed mad to those who claim to have sensed the actual presence of God. Phenomenological methods can be linked to measurement. For instance, phenomenological descriptions can be specified as individual scale items and responded to by participants.

Self-identification

Science

Many, but by no means all, psychologists identify their discipline as a science. By “science” they mean natural science. Hence, they seek nomothetic or general laws that govern psychological phenomena. These laws are discovered by means of true experiments, with participants randomly assigned to experimental and various comparison groups. At least one independent variable is introduced in the experimental group, and differences in outcome are assessed on one or more dependent variables. The variables are measured and the data analyzed by statistical methods. Hence, the establishment of a causal linkage between one or more independent and one or more dependent variables in a research design that is specified in enough detail so that independent scientists can replicate the results (Motterling 1999; Pashler 2001). This is the foundation for psychology as a natural science.

However, some psychologists consider psychology transcends natural science limitations and to be therefore argued for a unique or human science. Human sciences tend to employ nonexperimental methods. However, the use of a variety of nonexperimental methods is justified by these researchers on the basis of the unique nature of the object of psychological study (Miles 2007).

Religion

Few psychologists identify psychology as a religion. For many, psychology replaces religion as the proper explanation for human action.

Often, critics of psychology argue that many psychological practices parallel religious ones. For instance, mental illness is used as a description in place of sin. Some claim that a secular psychology worships the self and that a humanistic psychology itself functions as a religion. However, regardless of perspectives, most psychologists would argue that they seek to discover by appropriate methodological procedures factors that influence actions, affects, and beliefs rather than to accept answers based upon traditions or authority, whether faith based or not. For many psychologists, religious phenomena can be studied in their own right using methods devised by psychologists that allow for description and explanation, but are often methodologically linked to assumptions that exclude the transcendent. However, psychologists associated with human science assumptions can study experiences that include experiences of transcendence that can be described and studied in ways that do not reduce them to natural science assumptions. Perhaps, this is most evident in subdisciplines of psychology that assure that the clinician has undergone a healing experience (as in psychoanalysis) or in contemporary studies with entheogens where the researcher who has ingested entheogens also is involved in their scientific study by using both themselves and others as research subjects.

Characteristics

Research methods are distinct in that they document procedure by which results can be replicated. Whether from a natural science perspective or a human science perspective, methods are synonymous with procedures that can be replicated. Even procedures that are not publically observable can be replicated in an individual's own experience. For instance, there is good agreement on the existence of altered states of consciousness that can be both individually experienced and publically reported when such individuals answer questionnaires of scales designed to assess such states. Closely related to methodology is measurement, or the assignment

of numbers to concepts which have been operationally defined. For instance, if aggression is measured by self-report of willingness to harm another, one can identify someone as aggressive or not (nominal measurement) or as more aggressive than another (ordinal measurement). Perhaps more than other disciplines, psychology is unique in the range of methods it employs (Roth 1987; Todd et al. 2004). Areas of psychology can be identified by both topics studied (e.g., developmental or social) and methods employed (e.g., psychoanalysis or experimental).

Relevance to Science and Religion

Methodology in psychology is interested in religion as an object of study. As such, it applies research methods to religious phenomenon as it would apply them to any other phenomenon. For instance, one can study how religious belief affects behavior just as one might study how political beliefs affect behavior. Arguments within the discipline center on whether or not there are unique religious variables or whether or not psychological variables uniquely interact with religious ones. While most methodologists do not exclude any religious phenomenon from investigation, they are cognizant that they study the human response to transcendence, not transcendence itself. Religious phenomenon then must fulfill the same criteria that other objects of psychological investigation must fulfill insofar as psychology as a natural science is concerned. Thus, they must be able to be operationally defined, measured, and subjected to some degree of experimental investigation. However, psychology as a human science permits a wider range of methods, many of them descriptive and influenced by *a priori* assumptions. For instance, both cognitive psychology and psychoanalysis assume that many of the determinants of human action are unavailable to introspection or accurate self-report as they are not consciousness. However, cognitive psychologists are likely to use experimental methods to uncover these determinants while psychoanalysts use techniques such as dream analysis and free association. Phenomenological psychologists on the other hand focus upon

that which appears to consciousness and is assumed the determinant of action. By triangulating results from these three methods, a richer description and explanation of human action is possible than by an exclusive reliance upon one method and associated with a specific set of assumptions.

Sources of Authority

Depending on basic assumptions, different methodologies are acknowledged. For those who assume psychology is a natural science, only causal properties accepted by other natural sciences and integral to their nomothetic laws are accepted. For instance, cognitive scientists accept that neurophysiological processes are intimately linked with thought and that there is no thought without brain activity. Thus, the ability to identify causal determinant of cognitive processes such as variation in memory requires close cooperation between cognitive scientists and neurophysiologists. On the other hand, those trained in psychoanalytic techniques privilege the analytic process that they themselves have undergone as a unique method to uncover unconscious determinants of behavior. This is contrasted with a phenomenologist who seeks to describe what appears to human consciousness while bracketing any ontological claim to either the reality status of that appearance or its causal efficacy in human action. In this sense, the authority of any method is linked to the nature of the question that the method addresses. Perhaps a major distinction between subdisciplines in psychology is in the role of authority in interpretation of data. Many experimental psychologists place authority in methods and procedures that permit replication of findings by independent investigators. Psychoanalysis places authority in their own successful analysis, allowing them to interpret the actions of others by the use of the same techniques used in their own psychoanalysis, required before they can treat others. Those committed to hermeneutical techniques rely upon the insight achieved when a meaningful interpretation has been offered. However, regardless of the method, all assume that if

the individual will (a) share the same assumptions and (b) follow the same techniques, (c) then consensus will be achieved. In this sense, all subdisciplines in psychology appeal to methodology as a source of authority for conclusions reached.

Ethical Principles

Ethical issues are involved in all aspects of methodology in psychology. For instance, in experimental designs, the experimenter often presents a plausible cover story to guide the research participants. This cover story involves deception as to the true intent of the experiment. The experimenter must weigh the value of the results obtained by deception with the actual act of deception itself. Often, after the experiment is completed, participants are debriefed and told the real purpose of the experiment. Experimental psychology avoids some ethical issues when it focuses upon nonhuman organisms. However, even here ethical issues arise, including perhaps extreme concerns with the use of laboratory animals under any conditions for research purposes. A more balanced approach is the adherence to explicit ethical guidelines for use with both animal and human subjects that are required of psychologists who are members of the American Psychological Association. On the other hand, many human science approaches require self-disclosure, often only achievable in interpersonal relationships that are either explicitly therapeutic or involved with efforts at personal growth and self-realization. In these instances, when the therapist or guide is a licensed psychologist, ethics of confidentiality, while not absolute, are nevertheless assured. Finally, universities have internal review boards that must approve any research project, whether involving animals or humans, that is done under its authority.

Key Values

The major values guiding methodology psychology are the desire to know and, for some, the desire to apply knowledge to the betterment of

humankind for others. Researchers must of necessity be curious and have faith that underlying all human actions are homothetic laws that are both capable of being discovered and useful to apply to the betterment of humankind.

All psychologists have some degree of commitment to values that inform empiricism and rationalism. Empiricism assumes that what the senses reveal is both real and important. Some knowledge is empirical and cannot be known unless there is empirical exploration of natural phenomena revealed by the human senses. Rationalism seeks what is necessary, not merely contingent. Rationalism assumes that reason must be applied to sense perception to allow for rational comprehension of the necessary appearance of phenomena. Rationalists assume that they may be universals that apply across cultures and can be discovered by applying the powers of the mind to what is perceived by the senses. Finally, psychology need not deny revelation as a source of knowledge nor deny the power of tradition as a form of collective wisdom. There are psychologies that embed themselves within the values of various traditions, religious and otherwise. They use the values of these traditions to inform the direction and nature of their research and to direct the identification and nature of treatments. For instance, as psychologists, homosexuality is no longer a mental illness, but for some more fundamentalist religiously committed psychologist, it remains a sin. Psychology is unique in having to balance various values that can at times appear incommensurate. However, higher order unities can be achieved, as for instance, to hate sin is not the psychological equivalent to hating the sinner.

Conceptualization

Nature/World

Methodologist in psychology conceived as a natural science assumes either that persons are to be understood in terms of the natural processes that operate in all natural life forms that have evolved from the natural world. For instance, evolutionary psychologists interpret the emergence of many human tendencies as selected for the survival

value in increasing reproductive success. While humans may be conceived as unique, their uniqueness is due to the emergence of properties associated with such unique, yet natural qualities, such as language. On the other hand, proponents of psychology as a human science argue for unique properties associated with forces not recognized by natural scientists. Often, the proponents of these forces rely upon phenomenological reports of experiences, including apparitions and various spiritual entities, including God. Human science advocates tend to reject the principle of the exclusion of the transcendent that is adhered to by natural science proponents of psychology. For instance, human science proponents are open to the possibility that part of the experience of God comes from God.

Human Being

Methodologists that subscribe to natural science assumption tend to accept some theory of evolution as the overarching covering law to explain all psychological processes. Random variation and natural selection are sufficient processes for the ultimate determinants of human belief, action, and affection. Persons are viewed as distinct from other species but not unique. Religion may have evolved to give persons a sense of meaning and purpose that is compatible with reproductive success. However, gods are the creation of persons and do not exist as independent forces or causal agents. Human science advocates are more acceptable to processes and realities that are not accepted by natural scientists. Unique methodologies not applied to natural science objects are often appealed to in defense of the gods or even God as an independent causal force operating in the world. Again, such appeals use methods not part of natural science methodologies such as phenomenology.

Life and Death

Methodologists, who assume natural science stance, appeal to evolutionary theory both for the origins of life and for the necessity of death. Life need have no independent creator God and likely emerged from chance variation and natural processes. Life need have no purpose. Death is the fate of all life forms, both individually and perhaps ultimately collectively of the human

species. The cycle of life and death assures random variation and natural selection, allowing for the diversity of life forms. Religion is viewed as part of the psychological process of the denial of death, a fate of which only human species are self-consciously aware. On the other hand, religion may be selected for survival value, especially for those evolutionary psychologists who accept natural selection processes operate for groups as well as individuals.

On the other hand, many human science advocates find a reality in religious discourse that suggests the transcendence of death. Investigators of such phenomenon as near-death experiences dispute the ontological claims of such experiences, varying from those who view the experiences are evidence of oxygen-deprived dying brain fooled by its own hallucinations to those who are assured that they constitute evidence of transcendence. Methodologically, all that assured that we are beginning to identify the conditions under which such experiences are reliably reported, regardless of what ontological weight they ultimately carry. However, many who do not accept that psychology must restrict itself to a methodological naturalism utilize methods such as phenomenology and various forms of self-report to accept the ontological reality of what others simply identify as altered states of consciousness.

Reality

Methodological naturalists assume that matter is primary and that sense datum is the basic reality. However, modern science has made the concept of matter sufficiently mysterious, especially quantum physics, that psychologists can no longer defend methods restricted to prequantum physics. Many psychologists essentially adopt a neo-Kantian perspective in which reality as dealt with by psychologists is socially constructed. Most psychologists avoid claims as to the nature of ultimate reality.

Perception

Sensation and perception are among the earliest topics studied by psychologists. Sensation refers to the more proximate appearances, stimulated by senses. Perception is more of a purely

psychological construct, referring to how phenomena appear to persons. All perceptions imply particular frames or schema that organize sensations and create a phenomenal world whose relationship to a postulated external reality is always tenuous. While methodological naturalists seek some correspondence to reality external to the observer, phenomenologists are content to describe in detail the nature of appearances.

Time

Psychologists are more likely to focus upon the experience of time than objective measures of chronological time. Reaction time is used in a variety of ways to infer internal mental processes and states. The experience of time, often identified as duration, has little relationship to measured clock time.

Consciousness

Consciousness is a focus of psychologists who approach its study from a variety of methods. Some seek to correlate consciousness with neurophysiological processes while others advance the notion that consciousness can be studied as a phenomenon in its own right. Efforts to avoid dualism associated with Descartes are not fully satisfactory. Both awareness and reflexive self-awareness are seen as evolutionary emergents, leading some to postulate a cosmic mysticism in opposition to naturalism. The methods employed largely determine the nature of consciousness being postulated.

Rationality/Reason

Psychologists distinguish rationality from logic. Rational behavior is behavior done for a reason or purpose. The psychologist views behavior as rational that is empirically a means to a given end. This begs the question as to the reasonableness of any given or chosen end. While some psychologists view rational behavior as an ideal for humans, others find much of human behavior to be less rational than functional for survival value.

Mystery

Many psychologists believe that accurate understanding removes any mystery from what is explained. Others assert that even when

explanations are provided, something essentially mysterious remains. Often, the mere fact of emergent properties is claimed to be mysterious. For instance, even if one could explain how we are conscious that we are conscious beings remain mysterious. In the broadest sense, when all explanations are provided, the question why still remains, and having no further answer is perhaps the greatest mystery of all.

Relevant Themes

Methodology is a required course in most undergraduate and graduate psychology programs. However, it has become apparent that psychology has no privileged methodology and is characterized by methodological pluralism. Each method implies both a metaphysic and ontology so that psychology is not a single discipline, but rather a fairly loose coagulation of persons interested in understanding the human condition. The American Psychology Association has over 50 divisions, ranging from particular specialties closely aligned with psychology conceived as a natural science (e.g., experimental psychology or behavioral neuroscience and comparative psychology) to applied specialties (e.g., clinical or industrial organizational psychology). One could easily identify the limit and range of methods courted by members of each of these divisions. Some are obvious such as the experimental analysis of human behavior. Others reveal a quest for equal status based upon methodological assumptions. There is a proposal pending for a division of qualitative inquiry obviously to balance the emphasis championed by a division simply called measurement. Not only are the methodological commitments obvious in various divisions, the values championed are often obvious subtexts. This is especially the case in explicit interest groups such as Society of the Study of Lesbian, Gay, and Bisexual Issues and Psychology of Religion, which once was simply Psychologists Interested in Religious Issues. Likewise, one does not have to be a psychoanalyst to note differences in values between the Society for the Study of Peace, Conflict, and Violence: Peace Division and the Society for Military Psychology.

It is apparent that the large number of divisions of the American Psychology Association reveals values and methods that are complexly intertwined. Diversity can be seen not as a fragmentation into special interests but rather an enrichment of the discipline of psychology. It is unlikely that psychology will advance its understanding of humankind by demanding a single or even limited range of methods. Likewise, a variety of value-oriented approaches refracts what is otherwise seen as a simple white light. A current challenge of psychology is to integrate its own understanding of humankind with those of the great faith traditions' current, past, and future, religious and otherwise, in ways that do justice to the persons that psychologists study.

Mind Uploading

Robert M. Geraci

Associate Professor of Religious Studies,
Manhattan College, Riverdale, NY, USA

The belief that human beings can transmigrate into machine bodies. Mind uploading is predicated on the claim that human minds are patterns of neurochemical activity taking place in the body/brain. As that pattern could, in theory, be replicated in another substrate (a computer), the mind can be copied to this new home and acquire immortality – barring catastrophic destruction of the machines where the mind is housed and backed up. Mind uploading first appeared in A.C. Clarke's science fiction novel *The City and the Stars* (1955) but gained its first sustained scientific description in Hans Moravec's *Mind Children* (1988). Moravec described an operation whereby the brain is carefully dissected and its pattern replicated in a machine thereby "transferring" consciousness from the biological body. Subsequent mind uploading advocates have claimed that noninvasive brain scans will provide sufficient resolution for mind uploading (i.e., copying) without actually killing the biological origin.

Hamburg, Hamburg, Germany

Related Terms

Smṛti (Sanskrit); *Sati* (Pāli)

Description

Mindfulness is a quality of central importance in Buddhist meditation theory. The most basic nuance conveyed by the term *sati* or *smṛti* in its Buddhist use is a detached awareness of a situation, comprehensively capturing its internal and external aspects, in order to fully understand what is really taking place. This invests the cultivation

of mindfulness in the Buddhist traditions with a concern that bears considerable similarity to scientific investigation.

Mindfulness in its early Buddhist usage stands for an ability to fully apprehend, which at the same time bears a close relation to the ability to remember later what happened. Canonical definitions of mindfulness tend to highlight this recollective aspect, explaining that one who has mindfulness will be able to remember what has been said or done long ago (Trenckner and Chalmers 1888–1896, I, 356).

Further information on the significance of mindfulness can be garnered from a few selected similes found in the early Buddhist discourses. One of these similes shows that the Buddhist tradition to some extent identified the deployment of mindfulness as a scientific procedure. The simile in question describes a surgeon at work. In this context, mindfulness corresponds to the probe used to inspect the wound (Trenckner and Chalmers 1888–1896, II, 260), enabling the surgeon to gather the information for the proper treatment of the wound.

This in a way ground-preparing quality of mindfulness finds an echo in another image of mindfulness as the plowshare of a farmer (Feer 1884–1898, I, 172). In other words, mindfulness has an investigative quality to it, which turns up what has so far been unseen and thereby explores the situation for subsequent appropriate action, be this the planting of seeds or the treatment of a wound.

A somewhat different but complementary aspect comes up in one simile which compares mindfulness to a careful charioteer (Feer 1884–1898, V, 6). In other words, maintaining mindfulness while “driving” through life’s vicissitudes goes a long way in avoiding “accidents.”

Another simile describes a cowherd who earlier had to watch the cows closely to prevent them from straying into the ripe fields. After the crop has been harvested, however, he is able to relax and watch over them from a distance. The term used for this distant and relaxed watching over the cows is *sati*, “mindfulness” (Trenckner and Chalmers 1888–1896, I, 117). This image conveys nuances of a calm and detached observation from an uninvolved distance.

A closely similar notion can be seen in another passage, which compares the systematic development of mindfulness to having climbed onto an elevated platform or a tower, instead of being carried away by the stream of desire (Alsdorf and Norman 1966, Stanza 765). This image finds a complement in a stanza according to which mindfulness is what keeps the streams of this world in check, so that they can then be cut off by wisdom (Andersen and Smith 1913, Stanza 1035).

The function of mindfulness directed to the body in particular receives an illustration in a simile that describes a man who has to carry a bowl brimful of oil on his head through a crowd that is watching a beautiful girl performing a dance (Feer 1884–1898, V, 170). His task is to avoid spilling the oil, which requires close attention to the present moment and a good sense of balance.

In sum, the qualities associated in the early Buddhist discourses with mindfulness suggest a careful inspection of any matter at hand, combined with an inner distance or detachment that enables one to maintain one's balance at all times.

The systematic establishing of mindfulness (Sanskrit *smṛtyupasthāna*, Pāli *satipaṭṭhāna*) constitutes the seventh factor of the noble eight-fold path, which in Buddhist thought comprises the eight central requirements for progress to full awakening: right view, right thought, right speech, right action, right livelihood, right effort, right mindfulness, and right concentration (► [Truths, Four Noble](#)). According to the standard definition, the task of right mindfulness extends over the following four areas of meditative contemplation:

- Body
- Feelings
- Mental states
- Dharms

These four areas receive a more detailed exposition in a discourse that has been transmitted by different Buddhist schools with some variations (Kuan 2008). Common ground among these parallel versions is that contemplation of the body is undertaken by directing mindfulness to the anatomical constitution of the body, directing it to

the body as made up of material elements and to the decay of the body after death. This suggests insight into the nature and constitution of the body to be a central theme of mindfulness concerned with the body, thereby giving rise to a sense of detachment from the body. It is noteworthy that these exercises clearly combine an element of evaluation with the deployment of mindfulness.

Contemplation of feeling distinguishes the affective quality of experience into pleasant, unpleasant, and neutral types. The task of mindfulness here is to recognize the affective input provided by feeling during the early stages of the process of perception. The three types of feelings are further differentiated into worldly and unworldly occurrences, a distinction aimed at the difference between feelings caused by ordinary experiences and those related to renunciation and spiritual practice.

The task of contemplation of the mind is to recognize the presence (as well as the absence) of unwholesome states of mind, such as lust, anger, and delusion. The chief role of mindfulness in this context is to avoid the mind getting carried away by any particular train of thought, so as to be able to recognize clearly which state of mind underlies the thought process. Practice undertaken in this way lays bare the motivating forces at work in the mind. Contemplation of the mind also covers recognition of the presence or absence of higher states of mind, related to experiences that would take place during more advanced stages of meditation practice.

Dharms in Buddhist thought can stand for “elements” or “phenomena” in a general sense. Contemplation of dharms, however, has a somewhat more specific meaning. The common core of this way of developing mindfulness in the different extant canonical versions is concerned with detrimental mental qualities and beneficial qualities. The detrimental qualities are the five hindrances of sensual desire, aversion, sloth and torpor, restlessness and worry, and doubt (► [Hindrances \(Buddhist\)](#)). These need to be recognized when they are present, in order to enable their removal. The beneficial qualities are the seven factors of awakening, a set of mental

qualities that are diametrically opposed to the hindrances and held to be of particular relevance for successful progress to awakening. The first of these seven is mindfulness itself, which thus provides the foundation for the others. Building on the establishment of mindfulness, the other factors follow: investigation of phenomena, energy, joy, tranquility, concentration, and equanimity.

The purpose of developing the four establishments of mindfulness is mental purification and the realization of Nirvāṇa (Trenckner and Chalmers 1888–1896, I, 55). Another discourse indicates that whosoever have escaped, are escaping, or will escape from [the bondage] of this world, all of them do so by way of overcoming the five hindrances, well developing mindfulness in the above-described fourfold manner and cultivating the seven factors of awakening (Morris and Hardy 1885–1900, V, 195).

The practice of mindfulness and its medical effects has been investigated and studied for several decades, and mindfulness has by now become a prominent feature in modern health care.

Minimalism

Deborah Sokolove

Henry Luce III Center for the Arts and Religion,
Wesley Theological Seminary, Washington,
DC, USA

An approach to art characterized by reduction to the most basic elements. Minimalism arose as a movement in the 1960s and 1970s, with the works of such artists as Donald Judd, Ad Reinhardt, Ellsworth Kelly, Larry Bell, and Frank Stella. Minimalist art is typically monochromatic, often using neutral or primary colors in flat planes, untreated wood or canvas, metal, or glass. Minimalist artists strive for objectivity, often having their works industrially fabricated in order to reduce the emphasis on the artist's own personality or gesture.

[Mirror neuron mechanism\(s\)](#); [Mirror neurons](#)

Mirror neurons are a set of sensorimotor neurons, discovered almost 20 years ago in a sector of the monkey premotor cortex, known as area F5. These neurons have both motor and visual properties: they discharge when the monkey performs a specific object-directed action (e.g., grasping an object, holding it, manipulating it) but also when it observes another individual, a conspecific or an experimenter, performing the same or a similar action (Rizzolatti and Craighero 2004). Until some years ago, in the monkey, only mirror neurons responding during the execution and observation of hand object-directed actions were known (Gallese et al. 1996). More recently, mouth actions-related mirror neurons have been found. These neurons discharge during the execution of active ingestion actions of the monkey (mouth grasping of food, chewing, sucking, and so on). As for visual properties, most of them respond during the observation of ingestion actions as well; very few respond during the observation of mouth actions with communicative functions like lip smacking (communicative mirror neurons). It has been suggested that communicative mirror neurons may play an important role in the evolution of language.

Basically, mirror neurons allow the mapping of an observed action onto the same neural population which controls the execution of that

action. It has been shown that mirror neurons' function to match perceived actions with executed actions is not limited to the visual domain. Some of these neurons also discharge during listening to the typical sound of an action, like peanut cracking, without observing the action. These neurons were labeled as audiovisual mirror neurons (Koehler et al. 2002). This finding indicates that a percentage of mirror neurons is able to code the same action regardless of the sensory modality involved in its perception and eventually code an abstract representation of actions.

Since mirror neurons have been found not only in the premotor cortex, but also in other brain areas of the monkey such as the inferior parietal lobule, it is more appropriated to refer to them as a mirror neuron system (MNS) (Rizzolatti and Sinigaglia 2010).

The functional properties of mirror neurons have substantially widened the role of the cortical motor system. It has been proposed that the MNS is involved in coding the goal of an action and hence in understanding actions. Since an observed action is mapped onto the neural substrates controlling its execution and given the fact that the observer knows the meaning and the consequences of his own motor repertoire, this knowledge can eventually be transferred to the observed action. This notion is supported by the results of an experiment where the activity of F5 mirror neurons has been investigated in two different conditions. In one condition, the monkey could observe the entire sequence of an action; in the second experiment the monkey was prevented from observing the final part of the action by means of a panel. The animal knew that an object was hidden behind the panel but could not observe the experimenter's hand grasping it. More than half of recorded mirror neurons kept on firing even when the last part of the action was obscured by the panel. This has been taken to indicate that mirror neurons are able to complement missing information, namely, to deduce the last part of the action and to infer its goal. A very recent experiment has tested the activity of monkey mirror neurons during the presentation of movies showing grasping actions from different visual perspectives. The majority of the tested

mirror neurons exhibited view-dependent activity with responses tuned to specific points of view. A minority of the tested mirror neurons exhibited view-independent responses. It has been suggested that view-independent mirror neurons encode action goals irrespective of the details of the observed motor acts, whereas the view-dependent ones might either form an intermediate step in the formation of view independence or contribute to a modulation of view-dependent representations in higher-level visual areas, potentially linking the goals of observed motor acts with their pictorial aspects.

By means of noninvasive techniques it has been possible to investigate also the human brain and many studies have been carried out that confirm the existence of mirror properties also in specific regions of the human brain cortex. In a pivotal study using transcranial magnetic stimulation, it has been demonstrated that the excitability of hand motor cortex is enhanced when individuals observed hand actions with respect to a control condition. Later evidence in favor of a motor resonance system has been collected using different techniques spanning from neurophysiological to brain imaging techniques. Using magnetoencephalography and quantified electroencephalography, clear similarities between observation and execution of actions have been found. In particular a suppression of 15–25 Hz activity, known to originate from the precentral motor cortex, during the execution and, to a less extent, during the observation of object manipulation has been shown. A functional magnetic resonance imaging (fMRI) study investigated which brain areas are active during the observation of actions performed with different body effectors (Buccino et al. 2001). The results indicated that different premotor regions are activated according to the effector involved in the observed action. Thus, the MNS in humans shows a somatotopic organization that resembles the homunculus motorius described for the execution of actions. It has been demonstrated that the motor resonance encoded by the mirror neuron system depends on the motor expertise of the observer. In a pivotal study participants were presented with mouth

actions related either to food ingestion or to communication. These actions were performed by a human being, a monkey, and a dog (Buccino et al. 2004). The results showed that observation of ingestion actions activates the premotor cortex regardless of the species to which the individual performing the action belonged to, while communicative action observation was effective only when participants observed a conspecific (human being moving the lips as during speaking) but not when they observed a communicative gesture performed by the monkey (lip smacking) or the dog (barking). These results have been interpreted as evidence that the human MNS can match the observed actions on the executed ones only if the observed action belongs to the motor repertoire of the observer. These findings have been confirmed by an elegant study showing that expert dancers resonate more strongly when they observe another dancer performing the same kind of dance they practice with respect to the condition in which they have to look at a different type of dance.

Besides action understanding, the motor resonance mechanism embodied by mirror neurons has been also involved in coding the intentions of other people's actions and to some extent their emotions (Hari and Kujala 2009). In a recent study, participants were presented with the same action embedded in two different contexts (Iacoboni et al. 2005). In one case they observed an actor grasping a cup lying on a table set for breakfast while in the other case they observed an actor grasping a cup lying on the same table at the end of breakfast. One group of participants had to just observe the actions while another group was required to explicitly state the different intentions subtending the same action of grasping performed by the actor in the two different contexts. Results showed that there was no differential activation of brain areas between the two groups of participants, suggesting that the brain automatically extracts the intentions of observed actions together with the processing of motor aspects of those same actions and of the context in which the actions take place. Indeed, active brain regions in the two groups were those typically belonging to the MNS. In keeping with this,

in another fMRI study, volunteers were presented with video-clips showing actions that did reflect the intention of the agent (intended actions) and actions that did not (non-intended actions). Observation of both types of actions activated a common set of areas including the inferior parietal lobule, the lateral premotor cortex, and mesial premotor areas. When directly comparing brain areas activated for non-intended and those activated for intended actions three regions specifically emerged: the right temporo-parietal junction, left supramarginal gyrus, and mesial prefrontal cortex, known to be involved in attentional processes (Buccino et al. 2007). The converse comparison did not show any activation. Thus, our capacity to understand non-intended actions may be based on the activation of areas signaling unexpected events in spatial and temporal domains, in addition to the activity of the mirror neuron system.

Recently, researchers have investigated the brain structures possibly involved in emotion decoding, postulating that a mirror mechanism should play an important role herein as well. Brain imaging studies showed that a resonance mechanism similar to that described for mirror neurons in the motor cortex is at work in cortical areas controlling the motor responses that accompany emotions. When someone feels pain or disgust and when she/he observes in other people the emotional responses elicited by painful or disgusting stimuli, two main cortical structures are activated: the cingulate region and the insula. This finding clearly indicates that perceiving and observing someone else's feelings and emotions activate the same neural substrate which allows us to feel those same emotions.

Model

Anne L. C. Runehov

Department of Systematic Theology,
Copenhagen University, Copenhagen,
Denmark

Generally, one could say that a model represents something different than itself. A model can be defined as “a mental construction that based on the reality, reproduces the main components and relationships of the analyzed segment of the reality.” Simply put, models serve as tools for understanding reality. These models should not be regarded as entirely realistic but as simplified versions of the reality to be explained and, thus, always in some sense selective. Such comprehension of models has been used in empirical science since Galileo and are seen as *isomorphic representations* of reality, because they are simpler than reality but emphasizing its main features or, at least, those most relevant to the object of research (Cavero 2004). However, similar to the fact that there is no consensus concerning the meaning of model, there is no consensus concerning the meaning of isomorphism. Zbigniew William Wolkowski says that isomorphism may be defined in three different ways: Firstly, as “a one-to-one correspondence between elements in different systems such that the relationship between the elements is preserved”; (Wolkowski 1993, p. 61) secondly, as “a perfect analogy” (Wolkowski 1993, p. 61), that is, everything that the one system has, the other also has, and whatever happens in the one system, also happens in the other and conversely; thirdly, “whenever the symbols of one mathematical model stand in one-to-one correspondence with those of another, including the symbols of

relation, and whenever the relation is preserved when a pair of symbols in one model is replaced by their counterparts in the other, the two models are isomorphic” (Wolkowski 1993, p. 61).

Philosopher Ronald Giere does not understand *systems* in terms of *models*. He writes that “[instantial] models will [...] be isomorphic, that is, there will be a one-to-one correspondence between the elements of the different models” (Giere 1999, p. 42). However, the models in question must be *physical* and not merely mathematical (Giere 1999, p. 42). Cavero understand models as used in empirical science as *isomorphic representations*, while Giere makes a distinction between *interpretive or instancial models*. Instancial models provide an interpretation of a set of uninterpreted axioms, and *representational models* are “tools for representing the world” (Giere 1999, pp. 41–43). However, not all agree that models are isomorphic to reality and some make a distinction between models that (simplified and selective) *represent* reality, for example, simplified models of the universe; models that *replace* reality, for example, rats (instead of human beings) in medical research and *analogies*, for example, waves of water as analogies for waves of light.

Clearly, there is no real consensus on the understanding of isomorphism. Another idea is to distinguish isomorphic models by dividing them into *representative* isomorphic models and *structural* isomorphic models (Runehov 2007). From what is said above, it follows that representative isomorphic models should correspond one to one with the reality or substructure of that reality which it is meant to represent in such a way that the relationship is preserved.

A good example would be building models for *archaeological ships*. The constructors use precise details (material such as different sorts of wood, paintings, sizes of different parts, etc.) derived from the archaeological remains and preserved documentation of the ship to build the model to scale. Such models are used to rebuild the ship in full size, to put it in a historical museum or as research and study objects.

A good illustration of an isomorphic structural model is a city map. The different lines on the map represent the streets, railway lines, water, parks, and squares of the city. However, these lines (and thus the map) are not representative in the sense that they are reconstructed with the same details as the streets, railway lines, and so on, of the city. Structural models are also scale models, but they do not correspond one to one with the *real* city in the way the scale model of the ship corresponds with the *real* ship.

However, city maps are based on experience and measurements. For instance, we have the possibility to take satellite pictures, a possibility Gerardus Mercator did not have. Hence, the exactness of city maps (and other structural isomorphic models) varies with the amount and quality of information scientists have at their disposal.

Most but not all isomorphic models used in science are structural isomorphic models. Other models that are used are those with analogies and metaphors and *theoretical model* (Giere 1999). Clear examples of such theoretical models are Newton's laws, the Schrödinger equation, and the principle of relativity.

One variant of such theoretical models is known as the *deductive-nomological* (DN) explanatory model, which was created by Carl Hempel and Paul Oppenheim, explains events and things by way of scientific laws and theories. It is an idealized model that favors simplicity and aims to replace dubious and "ambiguous talk about the world with clear and precise talk about language (Hobbs 1993, p. 5). The DN model consists of an *explanandum* (a description of the phenomenon to be explained) and an *explanans* (a set of sentences being offered to account for it such as a scientific law). Thus, it is sentences that are explained rather than events. The explanation is deductive and ignores contextual factors (Hobbs 1993, pp. 3–10).

Another model used frequently in science is the *causational explanatory model*. That something x caused something y implies that x precedes y . Furthermore, if something x is true, then something y will follow, is logically valid. That the eight o'clock train was

delayed (x) caused me to miss my appointment with my son (y). However, it is important to note that causal necessity (in the causal model) is not equal to logical necessity, because causal necessity (in the causal model) is not equal to logical necessity, because causal necessity (in the causal model) only refers to a relevant causal factor that is specific for a thing to be in a certain way or for an event to happen. To illustrate this, if you hit the vase with the hammer, the vase will break, that is, your hitting the vase with a hammer causes the vase to break. According to the rules of logic, this implies that if the vase is not broken, you did not hit it with a hammer. This clearly is not what is meant by causal necessity as used in scientific causal models. Rather, what is meant is that the hammer and the vase are constructed of such material that when the hammer strikes the vase, the vase will break. The causing factor is the smash of the hammer being constructed in a specific way, striking the vase. An interesting distinction is the distinction between explanatory and exploratory models. Explanatory models are models as defined above which are used to explain that which is already known, for example, a model of the biological functions of the human heart. Exploratory models, however, may lead to further knowledge and insight, such as a model explaining the impact of rapid climate change on human behavior. This model not only explains expected changes in the climate but also explores the consequences this could have for human behavior. However, there is no real borderline between the two (Runehov 2007, pp. 48–51).

Model Theory

Xavier Caicedo

Department of Mathematics, Universidad de los Andes, Bogotá, Colombia

Description

In a broad sense, ► [model](#) theory is the branch of mathematical logic that studies the connection between formal languages and their interpretations, the latter construed as relational structures. In this setting, the structures obeying the axioms of a formal theory are called the “models” of the theory. More restrictedly, it means the study of models of ► [first-order theories](#) (Chang and Keisler 1973; Hodges 1993; Marcja and Toffalori 2003). Besides its foundational character, the model theory of first-order logic has become in the latter years one of the finest tools to solve classical mathematical problems, it has, moreover, strong relevance for other disciplines ranging from computer science to philosophy. Since the emergence of Syllogistics in Greece, the general trend of the development of logic was a gradual elimination of any ontological commitment, movement that culminated with the full formalization of mathematical theories at the beginning of the twentieth century. Preceded by some results of Löwenheim and Skolem, Kurt Gödel’s ► [completeness](#) theorem of first-order logic brought back semantics to logic and inaugurated model theory (Gödel 1930). His 1939 proof of the relative consistency of the axiom of choice and the continuum hypothesis by means of an inner model of set theory (the constructible universe) confirmed the importance of the model

concept. Model theory of first-order logic became a subject in its own in the middle of the twentieth century due to the works of Abraham Robinson (Robinson 1963) and Alfred Tarski (Tarski 1954), who introduced a wealth of new logical concepts and techniques to build and compare models. These fructified very soon in impressive results as Morley’s uncountable categoricity theorem, Robinson’s nonstandard analysis, Keisler’s ultrapower theorem, and the model theoretic solutions of various problems in classical mathematics, as Artin’s conjecture on solvability of homogeneous polynomial in p-adic numbers. Parallel developments were Cohen method of forcing to build models of set theory (Cohen 1966), Kripke semantics for first-order modal and intuitionistic logic, and Lawvere-Joyal categorical semantics for higher order intuitionistic logic (Goldblatt 1979). First-order logic is by far surpassed in expressive power by higher order logics, logics with new kinds of quantifiers, or (ideal) logics with infinitely long expression, but Per Lindström gave around 1969 a characterization of first-order logic as the most expressive containing the classical connectives and satisfying compactness and the downward Löwenheim-Skolem theorem, and similarly for other combinations of model theoretic properties. This gave rise to the systematic study of the hierarchy of logics partially ordered by expressive strength (Barwise and Feferman 1986). These logics restricted to finite models resulted in a useful tool to describe algorithmic complexity classes. In the last years, the main quest of model theory has been the classification of definable subsets of models of first-order theories (Shelah 1990), inspired in ideas of Morley, Shelah, and Zilber, which has allowed deep applications of logical methods in mathematics as Hrushovski’s proof of the Mordell-Lang conjecture in positive characteristic.

Self-identification

Science

Being part of pure mathematics, model theory self-identifies as a science inasmuch as

mathematics is considered a science. Being a division of logic, it shares the debate about the place of logic among the sciences and whether it is a science at all. In any case, its relevance for other disciplines, ranging from computer science to philosophy, gives it a special status among the sciences.

Characteristics

Model theory distinguishes itself from the other branches of logic (set theory, proof theory, recursion theory, nonclassical logics) by its object of study: the interrelation between syntax and semantics, particularly in the case of first-order logic. Although it shares with modern mathematics the classification of structures as a main object of study, it utilizes powerful logical methods unknown to ordinary mathematical practice.

Relevance to Science and Religion

The issue “science and religion” does not arise in model theory. Although a great part of the development of model theory could be considered philosophically motivated, this discipline is metaphysically neutral. On the other hand, model theory deals (in an avowedly limited but exact way) with concepts to which religion usually attributes great importance: truth, validity, worlds, knowledge, infinite, etc., being able to make subtle mathematical distinctions in these matters unavailable to theology or philosophy.

Sources of Authority

The only accepted validation criterion in model theory is mathematical proof or the explanatory power and productivity of proposed new concepts. The oldest and for many years the most influential periodical has been the *Journal of Symbolic Logic*. The book by Chang and Keisler (Chang and Keisler 1973) has been the most influential textbook. Some of the leaders who

signaled the conceptual bases of model theory and determined its development along the twentieth century are Kurt Gödel, Alfred Tarski, Abraham Robinson, Anatolin Malcev, Andrej Mostowski, Roland Fraïssé, Michael Morley, Richard Vaught, Jerome Keisler, Paul Cohen, Saul Kripke, William Lawvere, Angus Macintyre, and Saharon Shelah.

Key Values

Intellectual rigor, thirst for a description and explanation of all conceptual possibilities of being.

Conceptualization

Nature/World

“Nature” may have a local meaning: the complete system of the Earth, or a global one: the Universe. It could be construed model theoretically as the (local or global) bio-physic structure from which we are part and in which we act. In more restrictive terms, it would be a particular model of the physical theories in vogue, an incredibly complex differential or topological variety. “World” may be synonymous of nature, but it could refer technically to the following: (1) a particular model of an axiomatic set theory and (2) any one of the structures associated to the nodes of the relational frame in a Kripke model for modal, temporal, or intuitionistic logic.

Human Being

Mathematical logic and model theory pretend to understand the use of language for conveying information and drawing logical consequences, a characteristic human activity. Human imagination seems to be a kind of model-building ability. A reasoning agent plays an important role in the early interpretations of intuitionism, and several rational agents in the game semantics of classical and nonclassical logics. Although we may conceive objects exerting all observable functions of a human being belonging to various models of nature, these do not

capture the conscious human being able to place him(her)self outside of any model and to reflect about his(her) own reasoning activity.

Life and Death

Model theory does not address the usual conception of life and death attributed to biological beings. In models of physical theories, one may call life of an object the temporal interval on which the function representing it reaches a certain threshold. In models of temporal or intuitionistic logic, the life of an individual would be the domain of the local section representing it.

Reality

Between all possible models of nature, reality would be the “actual model,” but model theory does not seem to provide means of distinguishing it.

Knowledge

Model theory teaches that it may be impossible for a human being to know, even potentially, all properties expressible in a given language of a given structure. That is the case of the first-order properties of the arithmetic structure of the natural numbers, due to Gödel’s incompleteness theorem. On the other hand, Gödel’s completeness theorem says that the common truths of all models of a first-order theory are potentially knowable in a very precise and mechanical way, or by the time-honored methods of mathematical proof. Model theoretically speaking, knowing a theory would be not only deducing the consequences of its axioms but giving an account of all its possible models. Speaking about models of set theory, one may say that one model “does not know” certain property it has. For example, it may appear to be uncountable when viewed from *within* the model but to be countable to someone *outside* the model.

Truth

A well-defined mathematical relation between formulas and structures, usually inductively defined on the syntactical structure of the

formulas. If the structure A and the formula φ are in that relation, we say that φ is true in A (also: A satisfies φ , A is a model of φ). The truth of a formula is relative to the structure in which it is evaluated. In fact, mathematical truth does not seem absolute since it depends on the axioms of set theory one considers and, for a fixed axiomatics, on the model one considers.

Perception

Sensorial perception does not play a role in model theory.

Time

A dimension of the models of physical theories. In this conception, the models “contain” time, but they are out of time. In fact, all classical mathematical structures are similarly atemporal and their logical laws are immune to the structure of time. However, in certain nonclassical logics, time is a logical category explicit in the syntax, as in temporal or dynamical logic, or implicit in the way formulas are interpreted, as in intuitionistic logic. In this conception, logical laws may depend on the structure of time.

Consciousness

The consciousness phenomenon is an essential feature of our own experience, but it seems unreachable to any science because it does not seem necessary for any external description of the human activity.

Rationality/Reason

A human characteristic (see “[human being](#)” above). Mathematical logic attempts to describe and explain purely conceptual rationality. It has been successful with respect to the mathematical deductive discourse.

Mystery

Understood as things which cannot be known, even in principle, model theory provides many instances of “mysteries”; for example, the set of true sentences of arithmetic, the truth status of the continuum hypothesis, and the existence

of certain mathematical objects (certain great cardinals are colorfully labeled as undescrivable, ineffable, etc.).

Modern Appeal of Buddhism

Description

Amid the growing trend of secularization throughout the world, the appeal of Buddhism continues to increase. Buddhism, one of the oldest existing religions, continues to attract practitioners, not only in traditionally Buddhism territories, such as China and Japan, but also in the Western world. Important to this modern appeal, Buddhism gives the follower a complete and total way-of-being in the world that is directed toward the maximization of the individual's spiritual, mental, and physical well-being. Even the lay Buddhist adherent attempts to implement Buddhist thought and meditation in every act of living, thus allowing the *Four Noble Truths* and the *Eight Fold Path* to guide his or her life.

The Eight fold Path is developed by Siddhartha Gautama, and it is the way toward the liberation of the individual from his attachments and delusions. The ultimate goal is the cessation of suffering. They are broken up into three categories: (1) wisdom, comprised of right view and right intention; (2) ethical conduct, comprised of right speech, right action, right livelihood; and (3) concentration, comprised of right effort, right mindfulness, and right concentration. *The Four Noble Truths* are the basic formulation about suffering that was developed by the Buddha. They are as follows: (1) All of life is suffering. (2) Suffering is caused by attachment. (3) The cessation of suffering is possible. (4) The Eight fold Path can bring the cessation of suffering. These four statements represent the foundation of Buddha's understanding of human existence.

Buddhism ultimately developed out of Siddhartha Gautama's reaction to troubling aspects of human life. Having been born into a palace life-of-luxury, near the border between Nepal and India around 2,500 years ago, the *Buddha* or "enlightened one," was deprived of no material comfort, but was however lacking in the real human experience of suffering, until one day he escaped his palatial paradise and viewed human existence in all its ugliness. He was shocked by the site of the sick, the old, and the dead, and deduced that all of life was suffering. Furthermore, this suffering seemed to him to have no end, as the Hindu understanding of time posited the cycle of rebirth (*samsara*) that would ultimately lead the believer into another round of suffering. Somehow, for Siddhartha, this endless cycle of decay and death needed to be transcended. Having seen that the life of indulgence did not bring an end to suffering, Siddhartha attempted asceticism, but found no relief from suffering there either. Eventually, Buddha developed what he called the "middle way" – a path toward the "release" (*Moksha*) from of the cycle of rebirth, yet situated between the extremes of sensual pleasures and self-mortification. This new way of being-toward-enlightenment puts stress on practicality and simplicity in the contemplative life, while trying to avoid the extremes of asceticism and indulgence that ultimately become obstacles in the path toward enlightenment. Salvation from the suffering of the world comes through the "obtainment of enlightenment" (to literally become a Buddha) through the realization and understanding of reality itself. Once a devotee has obtained the status of a Buddha, he has achieved *nirvana*, or the ultimate state of "nothingness" (the literal absence of the former subject). Unlike the Abrahamic notion of heaven and hell, which can be understood as a physical place or a state of being, *nirvana* is explicitly understood as a state of nonbeing, and therefore not a place in space and time. Buddhists often use the metaphor of a candle flame literally being "blown out" to signify that what once was is now nonexistent or emptied.

Buddhism has a tripartite constitution, or the *Three Jewels*. This consists of the Buddha (Siddhartha), the dharma (Buddha's teaching and example), and the Sangha (community). In order to achieve enlightenment, a Buddhist practitioner must "take refuge," in the Three Jewels for their spiritual nourishment, for it is the Three Jewels that will aid the bodhisattva (an adherent prior to obtaining buddhahood) in obtaining enlightenment.

Despite the immense difference it has with traditional Western religions, Buddhism has attracted many new followers in the West and has had numerous revivals in its historical territories. For instance, in the West, the often perceived "impoverishment of meaning" through the increasing secularization of the modern world has generated a desire to reconnect with spiritual matters. Although consumerism has provided an abundance of material goods in wealthy countries, it has failed to provide existential meaning to many individuals' lives, which has ultimately led to their investigation of other religions. This need to explore alternative religious traditions has led many to Buddhism and to its nontheistic focus on the individual's redemption, spiritual well-being, and peaceful living. Its lack of theological concern, as can be found in the Abrahamic religions, has also allowed it to be practiced by those adherents of traditional Western religions as it causes no theological conflicts with their previously held beliefs about God.

Unlike many other religious traditions that are tied with nationality, race, tribe, or geography, Buddhism remains free from such restraints. In this sense, it can be considered a universal tradition that is adaptable to any and all cultures. Where others are tied to ethnic or nationality, Buddhists are free to invite converts from all nations and races.

Self-Identification

Science

Buddhism does not consider itself a "science" akin to modern natural sciences. Yet, unlike other religions, who see scientific explanations of reality as competition with their own, and therefore a threat, the history of Buddhism does

not bear such hostility to a natural or causal explanation of the physical world. With this in mind, Buddhism does see a close connection between its teachings on mediation, balance, and mental health to be precursors to psychology. Although psychology does not have an existential claim to salvation, it does share the concern for a peaceful and stable way of being in the world. This shared focus, centered on the individual, has led to some interesting work exploring their common concerns and common methods, especially in the book *Zen Buddhism and Psychoanalysis* by the psychologist Erich Fromm and Zen Master D. T. Suzuki. However, the same critique leveled against depth psychology or analytical psychology by cognitivists and behaviorists, that it is not scientific because there is no way to employ the scientific method upon its claims, would also be leveled at Buddhism if it were to claim to be a “science.” Most Buddhists claim that science is unable to answer all the questions and concerns about the human spirit, suffering, and the need for spiritual wholeness. These are topics in which science can uniquely contribute their own opinions, but are ultimately limited in their ability to adequately address the human being in his or her totality of experiences. Buddhism, while accepting many claims of the science, attempts to go beyond that which science can explain, and penetrate into the spirit of the human being, a realm that the natural sciences is unfamiliar with and incapable of understanding in a nonscientific way.

Religion

Despite the historical fact that the Buddha would not have claimed to have founded a “new” religion, the Buddhists of today understand that their explanation of reality and orientation of action fits the definition of a “religion.” In many ways, Buddhism is seen by their adherents to be a complete and total “way-of-being” in the world, as opposed to a “religion.” From the beginning of the tradition, Buddhism has proved to be a very fluid tradition. Early Buddhism’s minimal postulates have developed into much more complex forms of Buddhist practices, especially as it traveled farther from its

historical origins in the Indian subcontinent. Zen Buddhist practices, although rooted in Gautama’s basic postulates and practices, have developed a highly complex monastic life and monastic rituals, which bear little resemblance with early Indian Buddhism.

Characteristics

The modern appeal of Buddhism rests in its ability to answer the unanswered existential questions that still plague humanity in our secular age. Modern Western Buddhism is distinctively atomistic, focused on the salvation and well-being of the individual, which gives it great appeal to those socially mobile in the West where individualism is the dominant ethos. Furthermore, Buddhism is nondogmatic in comparison to traditional Western religions. Buddhism tends not to be threatened by the theological claims of other religion but rather adapts itself to various way of life. Because the Buddha does not claim to be a divine being, but rather a source of spiritual emulation, modern believers in Christianity, Judaism, etc., can incorporate Buddhist beliefs and practices into their daily lives without creating theological contradictions. In many ways, Buddhism has become a spiritual supplement for many believers in traditional Western religions. Indeed, it is well known that many Catholic and Anglican monks, including the famous Trappist monk Thomas Merton, have attempted to incorporate Buddhist meditation into their daily routines in the monastery.

Relevance to Science and Religion

Buddhism tends to be very ecumenical in its interactions with other religions, and many Buddhists have been open for a scientific study of religion. Although the methods of such study is secular and generally from the outsider’s approach, the ultimate goal has been a much more religious one. Buddhists tend not to want to deconstruct other religious traditions to find a flaw that they can drive a wedge through, but to find the commonalities between the religions in order to find common ground for discourse. Thus, similar to Islam, Buddhists are rarely effected by modern historical and textual research on their

tradition, but tend to be interested in the scientific study for the purpose of understanding the “other” and their religious worldview better.

Sources of Authority

Although certain sects of Buddhism have developed a sophisticated structure of authority, such as in Tibet with the Dalai Lama, Buddhism as a whole has never developed a centralized authority like the Papal authority in Catholicism, nor has it ever postulated a body of canon law that governs all the adherents uniformly. Because of this fluidity, Buddhism’s various branches have developed their own local systems of religious legislation, but all have attempted to root their authority within the basic structure of early Buddhism, that is, the Four Noble Truths, the Three Jewels, and the Eightfold Path. If there is anything that could be understood as supremely authoritative, it would be these three conceptions. However, due to this lack of formal structure, Buddhism by nature is very diverse, and often reflects the culture that it is in. This fluidity and diversity has been a strong factor in the appeal of Buddhism to postmodern thinking individuals in the West as it can easily adapt to Western culture.

Ethical Principles

A very important value that guides Buddhism is the ethic of nonviolence. Buddhism shares Hinduism’s belief in the cycle of samsara, and the negative effects of karmic energy. In order to avoid an unfavorable rebirth, the Buddhist adherent should live in such a way that nothing is harmed in his quest for enlightenment. This peaceful living, coupled with an intense concentration on the salvation of the individual from human desires and the power of rebirth, is the core value that guides the bodhisattva. As a missionary religion, Buddhism desires to bring more individuals into the community. For the Buddhists, the compassion for the suffering of others in this life is a motivational force to bring converts into the fold and to show them the way to end the suffering caused by desire. This urge to “save” the other from his present suffering motivates the believers to do missionary work.

Key Values

The most important value that drives Buddhists to do missionary work is the compassion they have for the other and the desire to decrease the suffering in the realm of living beings. They feel that they have the answer to the cessation of the horror and suffering of human existence and want to spare others from that fate. Therefore, social solidarity, rooted in eschatological concerns, drives the believers to spread their message to others.

Conceptualization

Nature/World

Buddhists are to live harmoniously within the natural world. Nature is to be respected by only taking from it what is needed for survival, while avoiding all acts of violence upon it. It is understood by most Buddhists that nature is amoral in and of itself; it lacks a morality as it lack agency. In this way, the Buddhists take a more pragmatic approach to the natural world: it is both beautiful and ugly, it is both productive and destructive, and it is both something to be admired as well as overcome. The natural world can be a major obstacle to enlightenment as attachment to this world is a source of desire and therefore suffering. Although the Buddhist is to live in harmony with this world, part of that harmony is nonattachment to this world and nature.

Human Being

Buddhists view human beings to be one part of an over system of life on the planet. Furthermore, they are one among many forms of sentient beings (beings with a mind and thought) that inhabit the earth. However, the special quality of humanity is that it is the only species that can break through the cycle of rebirth and obtain enlightenment.

Life and Death

Buddhists believe in the perpetual existence of life: that the individual will go through the cycle of rebirth forever until he or she is able to break that cycle through enlightenment. Once enlightenment is obtained, nirvana, or the emptied state of nonattachment, is the state-of-being in which the new “Buddha” lives. Since time is not

understood in a linear fashion as it is in the Abrahamic traditions, but is believed to be cyclical, Buddhists do not “fear” death in the same way as most Westerners. The cycle of rebirth (samsara), guarantees that the renewed existence of the spirit (atman) in the next life. If Buddhists fear anything about death, it is that they will not obtain enlightenment within a given life span before that particular death.

Reality

Like other religions, Buddhists see reality through a tragic lens. The mystical tradition of Buddhism and the prophetic tradition of the West both attempt to understand reality as the way things *are*, while focusing most of their attention on how the way things *should* be. Buddhists attempt to live within the world, without being a part of the world, in fear that to become fully absorbed or well adjusted to this world would have a negative eschatological effect on their lives. Buddhists emphasize the cessation of the suffering of reality by escaping its effects through a retreat into the Buddha, dharma, and Sangha.

Knowledge

Buddhists have maintained an almost exclusive concentration on spiritual knowledge: a knowledge that will lead them to enlightenment. Consequently, even when individual Buddhists engage in public discourse concerning political and economic matters, they do so from the position of spiritual value. The proper knowledge of the spirit and the human condition of suffering allows Buddhists to engage in public discussions of the good they wish to establish the social conditions that are best suited for the cessation of human suffering. Buddhists have relied on their vast resources of knowledge to argue their positions in their attempts to make their traditions attractive to outsiders. Indeed, the wealth of learning and the tradition of intellectualism in Buddhism has been a major factor in attracting converts.

Truth

Buddhists believe that absolute truth exists. They understand that there are universal norms and

laws that can be postulated by the humans such as Gautama Buddha and other Buddhas. These norms and laws are based within the experience of the Buddhas with cosmic norms. Truth can be established by spiritual experience, not only through empirical experimentation. Buddhist communities understand their founding figures to be exemplars of that truth and as such attempt to understand and implement their teachings into their own lives, thus embodying the truths that their founding figures articulated. Therefore, for Buddhists, the truth of Buddha, dharma, and Sangha can be verified through the personal attainment of enlightenment by the bodhisattva.

Perception

Buddhists remain skeptical of human perceptions, as they are easily misguided or misinformed. The Buddhist teachings for the attainment of enlightenment are used as criteria for which to judge the perceptions of the believers. Anything in contradiction, or that cannot be reconciled with the norms of the tradition, will be helpful in suspecting a misguided perception.

Time

In Buddhism, time is cyclical and constantly reoccurring. Time therefore is a force to be overcome by Buddhists. Often symbolically depicted as the demon “Mara,” representing death, Buddhists seek to overcome physical impermanence and time through the attainment of enlightenment.

Rationality/Reason

Buddhism’s relationship to reason and rationality, as a way of thinking about religion, really began in the modern period, when Buddhism met Western thought. Until that time, the mystical, not bound to formal logic or reason, was the creative force behind Buddhist cosmologies/theologies. Nevertheless, contemporary Buddhists understand reason to one of many avenues to understand human existence, the cosmos, and all that is. Yet Buddhists do not necessarily believe that reason is the only faculty that humans have for understanding existence, but is limited by its

very structure. In agreement with the Western philosopher Kant, Buddhists believe that reason cannot penetrate the thing-in-itself, that is, the phenomenon that as it is. Enlightenment, no skilled reason, reveals the mysteries of the universe in their totality.

Mystery

Buddhists understand that not all things can be comprehended or even known by human beings, and that there are aspects to existence that will always remain a mystery. This “mysterious” is not seen as a deficiency within the tradition but as an understanding that not all things can be grasped within the limitations of the human mind.

Modern Appeal of Islam

Description

Amid the growing trend of secularization throughout the world, the appeal of Islam continues to increase. Islam, the youngest of the three Abrahamic-monotheistic religions, is gaining converts in the West as it enjoys a revival in the traditional Islamic world. Important to this modern appeal, Islam understands itself to be a complete and total way of life, rejecting the separation of the private and public spheres. Taking Prophet Muhammad of the seventh century as their example, *Muslims* believe that Islam informs and guides every aspect of life. Today, much of the Muslim world is beginning to reject the claim that Muslims must live according to secular governments, economy, and education system, and are attempting to reintroduce Islam into the public sphere in total. For others, fearing the complete Islamization of society, these Muslims all appear to be modern fundamentalists. Nevertheless, even average Muslims who reject Islamic fundamentalism and extremism are calling for a new birth of Islam within society: that Islam should emerge once again at the center of Islamic life.

Islam was founded in the time of *Jahaliyya* (age of ignorance) in seventh-century Arabia by Prophet Muhammad ibn ‘Abdallah. In distinction from the social, political, and economic contexts that surrounded him, which was marked by slavery, female oppression, clan warfare, drunkenness, and polytheism, Muhammad attempted to introduce a radically different set of priorities. He focused on the emancipation of slaves, equality for women, unification of clans, sobriety, and strict monotheism; all of which were rooted in the Islamic imperative to create a just society. According to the tradition, *Allah* (God) delivered his divine message to the Prophet through the angel Gabriel (Jibrail) and was later compiled in what is called the Qur’an. It is important to note that Muhammad’s teachings and actions are not recorded in this sacred text, but in the books of *Hadith* (sacred traditions), which serve not only as a guide for Islamic belief in actions, but also as a tool in interpreting and understanding the Qur’an. Islam insists on five basic pillars: (1) the *Shahada*, or “declaration of faith.” It states, “There is no god but God, and that Muhammad is his Messenger.” (2) The Muslims are enjoined to make the ritual prayers called *Salah* five times a day at specific times. (3) *Zakat* (almsgiving), Muslims are commanded to designate a set portion of their excess income to the poor and needy. (4) *Sawm*, or fasting during the month of Ramadan, in which the believer does not eat, drink, smoke, or have sexual relations between sunrise to sunset for the entire month, and (5) Every Muslim, both male and female, have the obligation to make the **Hajj**, pilgrimage to Mecca, at least once in a lifetime. These five “pillars” represent the minimum qualification for a Muslim to identify himself or herself as a believer.

Since the twentieth century, Islam has attracted many new followers in the West and has had a revival in Muslim majority territories. Although some reasons for Islam’s new attractiveness are similar to other religions that are gaining converts, many are very different. For instance, the often perceived “impoverishment of meaning” through the increasing secularization of the modern world has generated a desire to reconnect with spiritual values.

Although consumerism has provided an abundance of material goods in wealthy countries, it has failed to provide existential meaning to many individuals' lives, which has ultimately led to their investigation of other religions. In the West, this need to explore alternative religious traditions have led many to Buddhism, and its nontheistic focus on the individual's redemption, and Islam, with its focus on social justice and its more traditional understanding of social values. Furthermore, the increasing Westernization of Islamic lands have fueled a reactionary return to traditional identity, often due to the fear of seeing the disintegration of the native culture. In the case of Muslim world, a much more militant form of Islam has often developed in reaction to globalization and Westernization.

Unlike many other religious traditions that are tied with nationality, race, tribe, or geography, Islam remains free from such restraints. In this sense, Islam is often considered a universal religious tradition. Where others are tied to ethnicity or nationality, Islam is free to invite converts from all nations and races.

Self-Identification

Science

Islam does not consider itself a "sciences" akin to the natural sciences. Yet, unlike other religions, which see scientific explanations of reality as competition with their own, and therefore a threat, the history of Islam does not bear such hostility to a natural or causal explanation of the physical world. Islam has had a long history of scientific discovery and development. Having spread from Arabia to Spain in the West, and India in the East within a few hundred years, the early Muslim community absorbed and augmented the technological, mathematical, philosophical, and medical knowledge of the territories they encountered. Muhammad himself commanded his followers to "seek knowledge from the cradle to the grave." The "scientific" advances of Islamic Spain, al-Andalus, which were rooted in many cases in Baghdad, were to be the foundational sciences in the European Renaissance and later the Enlightenment. Muslims understood scientific examination of

the physical world as a way of understanding Allah's creation. Unlike in medieval Christianity, where science was experienced as a competitor, the Muslims understood the exploration of natural phenomenon as a "religious science." Indeed, Muslims are often fond of saying that doing natural science is a way of understanding the divine, as to understand the divine's creation is a moment of comprehension of the divine itself. Bearing this in mind, Islamic society has often been at the forefront of the natural sciences, a historical fact so often forgotten in the West.

Religion

Despite the historical fact that neither the Buddha or Muhammad would claim to have founded a "new" religion, the Buddhists and Muslims of today understand that their explanation of reality and orientation of action fits the definition of a "religion." In many ways, both Buddhism and Islam are seen by their adherents to be a "way-of-being" in the world, as opposed to a "religion." Islam insists that it is a complete and total way of life, perfected by Prophet Muhammad. Consequently, as a "perfected" religious tradition, any later *innovation* (bid'a) within Islam is condemned. The opposite may be true in Buddhism, which from the beginning was a much more fluid tradition. Early Buddhism's minimal postulates have developed into much more complex forms of Buddhist practices, especially as it traveled farther from its historical origins in the Indian subcontinent. Zen Buddhist practices, although rooted in Gautama's basic postulates and practices, has developed a highly complex monastic life and monastic rituals, which bear little resemblance with early Indian Buddhism.

Characteristics

The modern appeal of Islam rests in its ability to answer the unanswered existential questions that still plague humanity in our secular age. Islam has a stubborn resistance to the secularization process and the atomization that follows it. It insists on the importance of the social dimension of life: family, society, community are utmost concerns. Because of this, it has great appeal to those who find themselves alienated within a secular and

individualistic culture. Furthermore, many modern people have lost faith in the social values that were once norms that society aspired to. The modern secular world has all but limited or nullified the truth-content of concepts such as truth, justice, and freedom; they have become catch words that have been exploited and drained of their meaning by politicians, advertisements, and militarists. The modern revival of Islam emphasizes the rescue of such values, principles, and concepts, by reintroducing them into popular discourse with their substantive meanings restored. For Muslims, these notions are deeply rooted in normative religious beliefs, emanating from the life of Prophet Muhammad, the Qur'an, and early Muslim community, and as such cannot be diminished of their meaning potentials. This stubbornness toward the functionalization and depletion of meaning potentials in normative values is very attractive to those who see life quickly becoming about *having* and not *being*.

Relevance for Science and Religion

There is not much interested in the scholarly study of "science and religion" within the Muslim world. The secular – outsider's – approach to the study of world religions is a foreign concept to Muslims who see all activities to be a form of religious life. In that sense, a Muslim could study religion and science from the academic angle, but he or she would still, at least in the Islamic sense, be doing a religious act; for study is a commandment of the divine in Islam. In this sense, the academic study of religion, which by no means is completely absent in the traditional Muslim world, is a religious act itself. Consequently, the advances in historical research on the origins of Islam have no real effect on the way Islam is understood or practiced by Muslims. As of now, the secular Western tradition of "higher criticism," which has examined various aspects of Christianity for centuries, has produced no measurable change in Islam or the Islamic world.

Sources of Authority

Islam has a comprehensive understanding of authority. The Qur'an, with the help of the hadith, is the textual authority, while the Imams

(pray leaders), 'Alims (scholars), and Shaykhs (preachers) represent the clerical authority. In Shi'a Islam, the minority sect of Islam, there is a very strict clerical structure within the 'ulama (community of scholars), with the highest possible position achieved being the Ayatollah (sign of God) and a Marja-i Taqlid (source of emulation). In Sunni (majority sect) Islamic history, the Khaliph (successor) of Prophet Muhammad held temporal and often religious authority over those in his dominion. However, the First World War saw the cancellation of the Khaliph in Istanbul with the destruction of the Ottoman Empire. Ultimately, it is the legal and theological scholars that hold authority within Islam, but their ability to impose their legal and theological rulings on the Muslim community is limited, unless through certain political structures such as the theocratic government of Shi'a Iran.

Both Sunni and Shi'a Muslims agree that the Qur'an is the highest authority within Islam because it is recognized as being the "kalam Allah," or the "speech of God." Muslims have been careful over the centuries to preserve the Qur'an in its original Arabic language. A translation of the Qur'an is not accepted as the Qur'an, but only a "translation of the meaning." The revelation that was given to Prophet Muhammad during his 23 years of prophethood was in the Arabic language; therefore, only the Qur'an in its original language has the authority that comes with being the word of God.

For the Shi'a, authority begins with Allah, who bestows a certain level authority on to Prophet Muhammad, who designated his cousin and son-in-law 'Ali ibn Abi Talib to be his successor, a claim that the Sunnis have rejected. The Shi'a also contend that the 'Ali's authority was passed down to his sons Hasan and Hussein, who would later pass down their authority to the following Imams. In all, the Shi'a believes that the last of the Imams, Muhammad al-Mahdi, remains the sole legitimate authority on earth, but he has been in "occultation" since 874 CE/AD.

Ethical Principles

In Islam, the most important value is that of radical oneness (tawhid) of the divine. The one

God of Islam commands his followers to be “*in* the world” but “*not of* the world.” With this radical monotheism comes a strict ethical code that is focused primarily on piety and righteous behavior. Islam, like Judaism, is an orthopraxis religious tradition that insists on ethical behavior based on the prophetic model of Prophet Muhammad. Furthermore, Muslims are enjoined to abide by the norms of the juristic code (Shari’a) that has been developed within the first centuries after the death of the Prophet, and continues to be a source of ethical and moral guidance. As an evangelizing religious group, Muslims desire to bring more individuals into the community. In Islam, this life is a test to determine whether or not the individual is worthy of paradise (jannah) that the divine is offering. In order not to end up in the hell-fire (jahennum), the Muslims attempt to spread Islam by way of *dawa* (evangelism). This urge to “save” the other from his or her future suffering in hell (Islam) motivates the believers to do missionary work.

Key Values

The most important value of Islam that motivates Muslims to do missionary work is the compassion they have for the other. They feel that they have the answer to the cessation of the horror and suffering of human existence and want to spare others from that fate. Therefore, social solidarity, rooted in eschatological concerns, drives the believers to spread their message to others.

Conceptualization

Nature/World

In Islam, nature is understood to be a creation of Allah; the Qur’an even encourages the believer to “look to nature” for the signs (proofs) of God are within it. Muslims historically have attempted to live in balance with the natural world: on the one hand, it is seen as a trust from the divine to be used by humanity, but on the other hand that same trust must not be violated by doing unnecessary harm to the planet. Furthermore, the depiction of paradise in the Qur’an is that of a garden, full of

wonderful foods, shady trees, flowing water ponds, etc. In essence, paradise is the natural world in utopian form.

Human Being

In Islam, humanity is a creation of Allah and is finite. There is a special relationship between the divine and humanity that does not exist with other creatures. Allah gave humanity the ability to accept or reject the divine, which determines one’s own fate in the afterlife. Muslims believe that Allah created all humans in a state of “submission,” only later do they decide to either rebel against the divine or accept their natural state of submission to the creator. Furthermore, humans have a special charge over the earth, as it is their trust and their responsibility to care for Allah’s creation. This comes with Allah’s granting humankind with the faculty of reason and sole the recipient of divine revelation; both demonstrate the creator’s favor for his human creation.

Life and Death

For Muslims, all life is created through the act of “willing” by the divine. The Qur’an says the creation comes about by Allah saying “be” and it is. Death is not supposed to be a fearful act in Islam, as it is a homecoming to the divine if the individual led a righteous life. However, the day of judgment, when every individual is confronted with a book of his good deed and of his bad deeds, and is asked to account for them, is a process that every human has to face. Furthermore, as a missionary religion, Islam sees the cessation of life as a possible tragedy or a cause of celebration; either the deceased passed on to a place of infinite torment (Jahennam), or is within the presence of the divine and his prophets (Jannah). Indeed, for the Sufis, mystic Muslims, death of a devout Muslim is described as their “urs,” or “wedding day,” as they are wedded to the divine postmortem.

Reality

Muslims often see reality through a tragic lens. The prophetic tradition of Islam attempts to understand reality as the way things *are*, while focusing most of their attention on how the way

things *should* be. Muslims, as instructed by Muhammad, attempt to live within the world, without being a part of the world, in fear that to become fully absorbed or well adjusted to this world would have a negative eschatological effect on their lives. Muslims insist on transcending this world (*dunya*) by altering and or modifying it to produce a more just society where righteousness and piety can be easily lived.

Knowledge

Islam has mandated the believer to acquire sacred as well as temporal knowledge, with the understanding that both are needed to produce a just society. Muslims have relied on their vast resources of knowledge to argue their positions in their attempts to make their traditions attractive to outsiders. Indeed, the wealth of learning and the tradition of intellectualism is a major factor in attracting new converts, especially among the educated classes.

Truth

Absolute truth exists in the Islamic concept of reality. Islam maintains the belief in universal norms and laws that can be determined by humans as understood by direct revelation from the divine to Prophets. The Muslim community understands Prophet Muhammad to be an exemplar of that truth and as such attempt to understand and implement his teaching and way-of-being into their own lives, thus embodying the truths that the last prophet articulated. For Muslims, the truth of Muhammad's revelation can be verified through the application of Qur'anic norms in personal and social life. The perfection of society and the individual comes through a righteous and thoughtful application of the Islamic ideals.

Perception

Although they do not reject the human intellect, Muslims remain skeptical of human perceptions, as they are easily misguided or misinformed. The sources for Islamic norms are in the Qur'an and are used as criteria for which to judge the perceptions of the believers.

Anything in contradiction, or that cannot be reconciled with the norms of the tradition, will be held suspect of being a misguided perception.

Time

For Muslims, time is not eternal as only the divine can claim to be such. Time is linear in the Islamic tradition, especially in regard to the human life. Humans are born, their life serves as a test, and their death brings them to judgment. Muslims understand that they can effect the occurrences and happening within time, but that time itself is entirely within the realm of other forces, that is, the sovereignty of the divine. However, the limited time in which the individual life exists is a cause of urgency to implement the theory and praxis of the religious traditions.

Rationality/Reason

In the Islamic tradition, reason and rationality, especially in their Aristotelian form, have been employed both in the realm of theology and law. Long before the Western Enlightenment, the Muslim world had been using formal logic within various disciplines, including math, sciences, medicine, geometry, architecture, etc. Furthermore, Islamic theology has been formulated through the use of reason and rationality. The Muslim mystics (Sufis) have pointed to the limitation of the use of reason to understand the divine and have insisted on the "nonrational" experience of the divine through mystic ritual. Reason, on the other hand, is understood to have limits within the Islamic perspective. In agreement with the Western philosopher Immanuel Kant, human reason does not give Muslims the ability to understand the divine as the "thing-in-itself." If humans could do so, their intellect would rival that of the divine's. Therefore, humans can rationally think about the creator and all that is created, but is reminded that the human intellect is allowed only to know that which Allah wants it to know. Anything beyond that transgresses the limitation of reason established by the divine.

Mystery

Islam understands that not all things can be comprehended or even known by human beings, and that there are aspects to existence that will always remain a mystery. This “mysterious” is not always seen as a deficiency within the tradition, but as an understanding that not all things can be grasped within the limitations of the human mind.

[Computational chemistry](#); [Quantum chemistry](#); [Quantum physics](#); [Theoretical chemistry](#)

Nowadays, one of the most important research fields in chemistry is the study of large systems. In this sense, one of the most active research areas is the field of supramolecular chemistry, chemistry of big molecules (Atwood and Lehn 1996), which involves the use of noncovalent interactions to assemble molecules into stable, well-defined structures and which plays an important role in biological processes. Thus, it is crucial to examine the interactions between molecules and their environment. Well-known systems include host-guest and protein-substrate complexes, molecular clusters, or simply molecules within their medium.

Currently, there is great interest in the theoretical study of supramolecular systems. Molecular modeling includes all theoretical methods and computational techniques used to model or mimic the nature. The techniques are used in the fields of computational chemistry and biology, drug design, and materials science for studying molecular systems ranging from small chemical systems to large biological molecules and material assemblies. Computers are required to perform molecular modeling of any reasonably sized system. The common feature of molecular modeling techniques is the atomistic level description of the molecular systems. This may include treating atoms as the smallest individual unit (molecular mechanics approach), or explicitly modeling electrons of each atom (quantum chemistry approach).

Molecular mechanics is one aspect of molecular modeling, as it refers to the use of classical mechanics or Newtonian mechanics to describe the physical basis behind the models. Molecular models typically describe atoms (nucleus and electrons collectively) as point charges with an associated mass.

For this purpose, molecular mechanics (MM) methods are the most widely used in treating such large systems. Unfortunately, in general MM methods do not accurately describe the geometries or energetics of intermolecular interactions. With no representation of electron density, many chemically important quantum-based effects are missed. Additionally, intermolecular interactions for a number of MM force fields are known to be poorly reproduced.

In MM treatments, atoms are assumed to be spherical. However, in some cases this approximation is inadequate such as when dealing with hydrogen atoms. Hydrogen possesses only a single electron, which is always involved in bonding to a neighboring atom. For this reason the electron distribution about the hydrogen nucleus is not spherical, which could affect MM description of the hydrogen bonds. Then special caution must be taken when applying MM methods to the calculation of hydrogen bonds (Jensen 1992). Although MM methods do not consider time, there is a version of them that models the behavior of the system with propagation of time. This method is known as molecular dynamics. It involves solving Newton's laws of motion, principally the second law: $F = m \cdot a$.

Other methods like semiempirical methods employ approximations to accelerate solution of the Roothaan-Hall equations; thus, they are quantum mechanical in nature and are an improvement over MM methods in accounting for quantum phenomena. However, empirical solutions are substituted for the large number of multi-electron integrals, and these are parameterized to reproduce experimental observables for a large number of molecules. These approximations sharply limit the precision of semiempirical methods, particularly in treating systems that were not present in the initial parameterization procedure. Among the most widely used semiempirical methods are

AM1 (Austin Model 1) (Dewar et al. 1985) and PM3 (Parametric Method 3) (Stewart 1989). A concern in applying these semiempirical methods to supramolecular problems lies in the fact that they were parameterized to reproduce molecular rather than intermolecular properties.

Over the last few years there have been some efforts (Bernal-Uruchurtu et al. 2000; Repasky et al. 2002; and much more) to improve treatment of the core parameters in semiempirical methods that play a large role in the non-reproducibility of experimental data. One particular problem of semiempirical methods is that they present an unphysical stabilization effect for short-range H...H interactions (Casadesús et al. 2004).

In the continual drive to treat ever-larger systems with ever-greater precision, theoretical chemistry has turned its interest to the so-called hybrid methods that use multiple approaches of varying accuracy and cost to simultaneously treat different parts of a system. The use of hybrid methods is very important for the study of large molecules or supramolecular systems (Casadesús et al. 2002). Within these schemes the computational cost diminishes considerably and the entire system can be considered without needing to generate simplistic model systems. Among these hybrid approaches, the ONIOM method developed by Morokuma et al. (Dapprich et al. 1999) is especially appealing as it can combine any quantum and MM method simultaneously at different parts of the same molecular structure.

To conclude, molecular modeling methods are now very often used to investigate the structure, dynamics, surface properties, and thermodynamics of inorganic, biological, and polymeric systems (Casadesús et al. 2006). The types of biological activity that have been investigated using molecular modeling include protein folding, enzyme catalysis, protein stability, conformational changes associated with biomolecular function, and molecular recognition of proteins, DNA, and membrane complexes.

their effects or significance within regulating functional circuitry in the peripheral nervous system (PNS) or central nervous system (CNS) (Kandel, 2000). Methodologically, MN aims at identifying the physiological role of one variable, one molecule, in a particular assay, most commonly by expressing or silencing a particular gene or protein. MN is different from (general) neuroscience by focusing on molecular aspects of scientific questions even though the general goals of analyzing complex phenotypes are the same. Although the term “molecular” is not specifically limited to one class of molecules, most frequently, recombinant DNA technology is used to specifically probe the effects of regulating its expression and monitoring a specific readout.

Self-Identification

Science

Molecular Neuroscience identifies itself as a science by strictly relating to empirical methods for generating insight and by adhering to material evidence, that is, the description of phenomena by direct or indirect sensual, interindividually exchangeable experience, and more specifically in the context of science by performing controlled, repeatable experiments examining as few variables as possible, at best one. The subject of MN is the central and peripheral nervous system, its organization, output, cellular, and molecular basis.

Characteristics

Molecular Neuroscience states that molecules are the ultimate causal effectors in events of the peripheral and central nervous system, its cells, and molecular and functional circuitries. MN is distinct with its methods, its attempts to modify only one molecular variable by mutation, overexpression, knockdown, or silencing of a protein or gene, and with observing the ensuing effects that can be simple or complex. The prevailing MN method of varying only

Molecular Neuroscience

Carsten Korth

Department of Neuropathology, Heinrich Heine University of Düsseldorf, Düsseldorf, Germany

Description

Molecular Neuroscience (MN) is the systematic and scientific study of specific molecules and

one variable at the time is thought to be particularly suited to uncover causal relationships in distinct circuitries of the functioning CNS and PNS or their components. Of note, this is not to mean that MN's method is limited to deterministic relationships, that is, the calculable and possibly hierarchical chain of events. MN also comprises nonlinear dynamic patterns.

Relevance to Science and Religion

The principally different methodological approach by which MN defines the world or reality leaves at first sight only limited overlap with what is called "religion."

There are, however, indirect touching points where MN and ethics/religion encounter:

- Experimental freedom in MN is not unlimited: by society's convention, for some experimental methods including the fields of animal experimentation, human-animal chimera, human embryonic stem cells, and experimentation with humans or human materials, limitations are implemented by ethical values, many of which have historical origins in societies' religions. In that sense, ethical values relating ultimately to religious beliefs do influence the field of MN and its experimental space.
- We assume that religion is an experience/behavior confined to humans. Therefore, MN can only answer this question in the context of human MN. Here, however, religion or religious experience relates to a complexity that is currently not amenable to systematic investigations. In a few studies, neuroscience has investigated mental states and religious experience from a behavioristic point of view, that is, the religious beliefs from others are taken as descriptions of reported inner states and can be correlated to biological markers, for example, to regional blood flow in distinct areas of the brain. Accordingly, religious experiences are understood to correspond to particular activation patterns of the brain. Here, MN is

attempting to make the physiological basis of religious experience intelligible but does not make statements about its contents.

Sources of Authority

The main source of authority is the community of current molecular neuroscientists present in globally organized conventions, organizations, peer-reviewed publications and grants, as well as academic teaching.

This authority is obviously in steady flux and historically rooted in the beginnings of using molecular tools for the investigation of the nervous system like with Rita Leve-Montalcini and the discovery of nerve growth factor, the advent of recombinant DNA technology, or many others.

MN is a subdiscipline of neuroscience which has still the main authority on the complex read-outs used by MN. Many techniques and methods used in MN are also from neuroscience, but with a stronger influence of molecular biology, protein biochemistry, and genetics.

Ethical Principles

Ethical principles that guide MN are ultimately the responsibility of the individual MN researcher who on a day-by-day basis has to decide whether his research is in accordance with general ethical agreements and conventions within the social context in which the individual MN researcher is living and performing his research. These permanent evaluations obviously depend on the education and values that have been received during the years of upbringing and education in society and are thereby rooted in the cultural and religious traditions of society. In the Western world, our current predominant human and animal rights have their origins in the religion of Christianity.

These ethical guidelines have been institutionalized by official conventions like the Declaration of Helsinki for experimentation involving humans, European or national laws, grant agency directives,

and other implementations of society's checks and balances, as well as control mechanisms.

Key Values

The key value is the absolute primacy of the truth of experiments, that is, to regard the experimental outcome as the supreme element of constructing the MN scientific reality. To achieve this, MN researcher and the MN community adhere to secondary key values like methodological diligence and thoroughness, frankness and honesty of discourse and data publication, as well as ingenuity of solutions and moral integrity.

Conceptualization

Nature/World

Nature/world is defined as the space of material things or phenomena that can be assessed by empiric, that is, direct or indirect sensual experience or experimentation.

Human Being

The human being is the result of an evolutionary process leading to the most complex form of life with the most complex and versatile CNS. It is recognized that, beyond MN, through the CNS of human beings, emergent phenomena like cultural evolution have originated which actively feed-back on the CNS and possibly on consciousness. But empirical research in this area, certainly in the context of MN, has been difficult and sparse so far.

Life and Death

Life is seen as the result of an evolutionary process from the level of prebiotic molecules to cells, multicellular organisms, and species. It is seen as a principal continuum from anorganic to organic molecules, compartmentalized molecule assembly to self-replicating molecules and cells. Genes are seen as the minimal unit of selection in the tripartite evolutionary process of variation, selection, and heredity in the so-called Modern Synthesis of Darwinism, combining insights

from classical Darwinian evolutionary theory with recent ones from molecular biology.

Life of a human being is thought to start upon the fusion of the egg from the mother and the sperm cell of the father and its first successful mitosis. Death of a human being is its inability to permanently maintain an independent metabolism.

Reality

On the level of interindividual space, reality is seen as the space of intelligible materials and events accessible by empiric as the prevailing method of MN. Reality is set equal with nature/world (see above).

On the level of individual brains, for example, during the scientific discourse between MN scientists, it is generally accepted that different realities within different observers can exist and lead to different conclusions even though the same experimental methods have been used. In that sense, reality, reflecting the entirety of an individual's perspective on the world, is seen as something relative and subjective. For experimental procedures exploring individual reality, for example, in primates or humans, a behavioristic attitude is preferred, that is, only the observed (motoric) behavior is taken for real, not any assumed intentions of the affecting animal or individual.

Knowledge

Knowledge of an individual or a community is seen as the ultimately finite (although huge) accumulation of experiences, descriptions, and documentations on phenomena that are interchangeable between individuals, that is, by language, writing, or reading.

Truth

Truth of a fact in MN is seen as evidence that is verifiable by experiments or sensual experience.

Perception

MN sees perception as an outside signal that is able to elicit a molecular response in signaling circuitry of a dedicated sensory cell. In MN, perception does not have to be a conscious

experience but can involve unconsciousness responses as well as lower organisms or species.

Time

Time is accepted as a fundamental variable of physics and in most biological experimental settings handled as a linearly and continuously progressing variable (objective time).

For purposes of computational modeling in neuroscience, time is sometimes divided into subsequently following time frames to simulate a sequence of states, for example, of neuronal networks. Here time is merely seen as defining the directionality of a sequence rather than a linearly progressing continuum.

Since neuroscience's subject includes the CNS and also an individual's experiences and time perceptions, time perception or time assigning experiments with nonhuman primates and humans have also led to the notion of subjective time with intriguing and still unresolved results (see, e.g., the work of Benjamin Libet, Libet 2005). Here subjective time perception is ultimately seen to be able to deviate from objective time.

Consciousness

Consciousness is seen as an emergent phenomenon of the brain with several definitions. A more narrow definition of consciousness includes a reaction of an organism to a perceived stimulus that it can reflect on. Unconsciousness is often set opposite to consciousness. An example is the phenomenon of blindsight where during cortical blindness (e.g., due to a stroke) and with intact eyes, clear motoric reactions can be evoked without becoming conscious for the affected individual.

One problem with a definition of consciousness is that its borders are not well-defined, for example, when a human being or a nonhuman primate becomes self-conscious during development. Recognition of oneself in a mirror is evidenced by particular behavioral reactions in humans or nonhuman primates and is generally seen as a sign of self-consciousness.

"Theory of mind" is a consciousness-related construct of an individual's ability to attribute of mental states to others. It is one's awareness of the other individual's awareness of oneself.

This concept has been linked to higher cognitive functions like consciousness. It has recently been discussed whether a specific cell in the premotor cortex, the mirror neuron, is a precursor of a physical correlate for a theory of mind since it is activated by both motoric actions and the perception of the same motoric action in another individual (Rizzolatti et al. 2008).

Rationality/Reason

Rationality/reason is the computational method necessary to link the empirical observations from experiments into causal relationships and algorithms. Rationality/reason is a cognitive/executive function of the highly developed brain and dependent on consciousness, that is, a reflection of a phenomenon.

Mystery

Mysteries in the religious sense, that is, as passive experiences of a divine, unexplainable message, are not accepted in MN. In common language, a "mystery" is meant to designate an unexplored phenomenon that is worth being tackled by experimental approaches.

Monism

Iveta Leitane

Department of Philosophy, University of

Cologne Research Associate, Cologne, Germany

The word “monism” does not have a clear-cut meaning and its content has been subject to frequent change and reformulations. Thus, there is disagreement what monism is actually about. On the one hand, monism – when related to religion – was suspected of being too philosophical or rationalistic to express the core essence of some religious systems (Hinduism as one of the main candidates for being a monistic religion). Not all monistic religious systems obviously hold to be ones and at a closer scrutiny do acknowledge their monistic character depending on how the rational element is represented in the unity to be achieved (The terms came under closer scrutiny like “desire to identify itself,” “permanent union,” “realize the underlying unity,” etc.). The reason for introducing the term “monism” was to offer a consistent scientific worldview, not divided in scientific and religious competence fields. Though monism was suspected of rejecting the personality of God on one hand and self-sacrifice on other hand, both believed in religions like Christianity, Judaism, and Islam. And the controversy about self-sacrifice and self-fulfillment belongs to the lively discussed issues since 9/11. Monism was attributed in Christian scholarship of the nineteenth century to Asian and so-called pagan (tribal) religions. Both attributions were called in question. The attributions of speculative (philosophical) terms (monism, dualism) to phenomena like “mythic worldview” appeared to be inappropriate. From a strictly philosophical point of view, any monism is only partially so and therefore not monistic enough, remaining conflated with dualistic elements. One might further ask: What are the reasons for introducing dualistic elements in a system conceived of as monistic in other respects? Oneness by the negation of the difference and conflation into one are an equally

important point of disagreement. It depends on whether the involved dualities are mutually exclusive, coextensive, or codependent. There is a strong commitment to endorse the monistic worldview for reasons of scientific consistence. But what is understood as scientific depends on the dominant paradigm. For modern science, it has been a mechanical explanation and the use of mathematical models. And any attempt to make the worldview more scientific and therefore monistic means to adjust it to this dominant model of explanation as close as possible. The preferred way to fill in the gaps in the nineteenth century was to employ the notion of development. The problem with the scientific furnish of monistic attempts is that the required unity cannot escape some religious or mythological imports anyway. Darwin was just as unable to overcome some background assumptions of theological origin. Emphasizing the creative role of natural selection, he unwittingly personifies it and unconsciously endows the natural selection as the keystone of his monistic view with features that makes it similar to the Creator (infinitesimal changes taking place in very long periods of time, identifying with the standpoint of God by evaluation of evolutionary changes and their “appropriateness”) (Nelson 1996). While trying to unite or reconcile science and religion, the monistic enterprise should respect both the paradigm procedures for contemporary science and the existing ways to define religion within a given sociocultural whole. No wonder that there are many kinds of monism, given the diversity of principles which are seen as conflicting and in need of being united. The value of monism can equally vary. The need for radical changes in the existing thought system or worldview might articulate itself as the need for emphasizing or introducing elements of dualism. No wonder that the father of modern thought is the dualist Descartes, or that the father of Protestant Neo-Orthodoxy – Karl Barth, etc. Some sociocultural support for monism might be detected in Enlightenment and post-Enlightenment elites and their distanced attitudes to society while dualism was taken up by elites coming from socially lower or middle strata in societies of radical or rapid changes

(revolutions, etc.) and pluralism sometimes is advocated as a worldview of liberalism and democracy.

The term was coined by Christian Wolf in the eighteenth century and designated that philosophical system which allows for only one kind of substance. Monism is a model of explanation and substantiation that rather departs from coexistence of different opposed forces, principles, or states and proves, that and how they lead to unity. The term *advaita* (non-dual) might be a good example of this negative point of departure in the constitution of the monistic system. Monistic teachings or models are opposed to the dualistic approach (assumption of two opposing and independent of each other basic forces, principles, or states that form or determine the world; Zoroastrianism, Manichaeism as examples under religions; mind-body dualism in philosophy) and pluralistic view (reality is derived from or comprises many independent entities). Sometimes it is referred more concretely to belief in the unity of mind and matter, both being two different instances or modes though. Caution is expressed not to confuse non-dualism or non-dual knowledge (directed against duality) with monism in attempting to grasp the essence of Hinduism (Advaita-Vedanta, Milne 1997). It is not an objective description of phenomenal existence that is envisioned by this kind of knowledge. The non-dual knowledge that is derived from the authority of Scriptures (*sruti* teaching reality is one) transcends the grasp of reason and refers merely to the Self, in which the knower is the same as the known. The one Reality only appears as multiple realities by identifying itself with mind and body. Duality being an experiential fact (dual appearance of reality) evokes a religious desire to know the underlying unity, the ultimate nature of the real.

All monisms attribute oneness only differing in what they target, how they count or what are the units, and how the attribution of oneness itself is performed or understood (Schaffer 2007). One can discern existence monism, which ascribes the existence to one object, and priority monism, ascribing priority to one token existing among many. Existence monism maintains that only

one concrete object exists. Priority monism holds that but one object is basic, others being part of it as a whole. The presuppositions of notions like “basic” are generally not explicated. Religious assumptions and beliefs may equally infiltrate such assumptions. Existence monism might be materialistic, idealistic, or neutral (meaning something deeper). There are no strong philosophical arguments against priority monism, just on the contrary – there are some in favor of it, especially from emergence and from gunk. The argument from emergence is made by way of quantum mechanics, maintaining that the whole is emergent due to quantum entanglement and therefore prior to its parts. In belief systems there may exist value-monism, meaning ethics that recognizes only one thing as having value (e.g., duty, happiness, etc.). The distinction between respects (existence, priority, value, etc.) in which the unity is thought or otherwise achieved may be a good tool to get rid of some difficulties in consistent representation of religions possessing monist, pluralist, and dualistic representations alike. This distinction may be useful for the way the unity of Divine person against its Trinity is represented in Christianity, or for the way the Unity of God is thought of in Judaism though there are strong dualistic elements in it (radical monism of Rav Kook). It seems that all religions maintaining transcendent transcendence (against the immanent transcendence in immanent monism or immanent pantheism) are bound to break with a monism which is strong in all respects. Taking issue with concrete monistic and dualistic or pluralistic tensions within religions themselves accounts for conceptualizing in which respect monism has to be kept and remains fundamental in every concrete constellation.

There may be different mixtures of monistic and dualistic determination systems. Dualistic overtones might be detected even in such a paradigmatic monist as Parmenides (thought vs. doxa). A striking example is late antique Gnosticism. The split in spiritual and material components has to be overcome in a monistic way, in order to regain unity with one origin or even with one divine source (Goldammer).

Another example is the dualistic monism of Zhenyan tantric school. There are also mixtures of monistic and pluralistic models. Spinoza's monism is that of one substance and pluralism of infinitely many attributes. David Lewis' view (1966) of universe is based on pluralism and manifests itself as a pluriverse (against monistic universe). The mixture of terms does not mean in this context that the system should be incoherent. There are attempts to reduce the speculative outlook to the sociological. Mary Douglas gave a political or anthropological twist to the theological and religious interpretation: philosophical and theological discussion about relationships of either principles or forces only arises when the relations between subgroups alienated to society become an acute political problem.

Although the notion might be traced back to the Greeks (Parmenides, Platon, Plotin, Empedocles, Heraclitus, all distinctive for their own peculiar dualities), the term is associated with the movement in the late nineteenth and early twentieth centuries to unite science and religion through a unitary view of nature. Attempts have been made to stress the close connection between monism and (natural) science. Unity of Science movement (established by Otto Neurath) sought a common empirical attitude toward all the sciences and strove to develop a single, comprehensive scientific language referring to itself as a "Monism free from Metaphysics." It was accused of reductionism. German evolutionist Ernst Haeckel (1834–1919) defined monism as based on one common fundamental law that emphasized "the essential unity of inorganic and organic nature" (Haeckel 1894). His "monistic Religion" set for its task to free science from the restraints of "dualistic" Christianity with its doctrine of creation, of metaphysics and irrationality. Dualism was conceived in the sense of opposing (religion) to science and therefore monism acquired some antireligious impulses. Haeckel postulated that all organic matter was sensate and had evolved from cell-soul to human soul. He actually had the conviction that one spirit lives in all things. Matter, energy, and Psychosoma (world soul) were three aspects of the Trinity of substance set up by him.

The missing link in progression between inorganic and organic matter was postulated to be the cell-soul. Soul-life operated through the same laws of psychophysics. Monism has to unite idealism and materialism, spirit and matter through the Monistic Law of substance. He saw in the "theory of descent" and in view of spontaneous generation appropriate tools for explication of this genesis. His general philosophy of nature linked God to the eternal persistence of matter and energy throughout the universe and it was the law of substance, the supreme and universal law of nature that enabled such a link. Science needed religion (or rather forms of scientific faith) in order to fill in the gaps in existing knowledge with the help of theories as a logical aid when empiricism failed. Actually it was an attempt to redirect religion into monistic direction. This task, given the ever-changing agenda of sciences, appears to be a permanent one. It was God that in Haeckel's book "The Riddle of the Universe" (Weltraetsel 1899) (being rather the riddle of substance) was defined as the "universal substance," or "divine essence of the world." The book was influential but it could not serve to unify all monists. Haeckel's monism attracted followers among scientists (including Wilhelm Ostwald, Ernst Mach, and August Forel) and people among the educated lay public. In 1906, the German Society of Monists (Deutsche Monistenbund) was founded in Jena and counted among its members over 4,500 individuals. Haeckel insisted that the Monistic Religion was to be recognized by the state. He did not approve of the direction of *Monistenbund* toward antireligious stance, also maintaining that since knowledge was a "physiological process of nature," distinctions between "religion and philosophy" were artificial as well. In the Anglo-American world, monistic philosophy was popularized through the journal *Monist*, founded in 1890 in Chicago by the German émigré Paul Carus. Carus understood Monism as a Religion of Science and viewed science as a religious revelation. For him the task of Monism was to reconcile science and religion by creating a "scientifically tenable conception of God" and to build up a "new scientific

theology,” by making God and “moral law” the subject of scientific scrutiny. Carus found in Haeckel deification of matter and energy and insisted that God of science is the law. That was the reason why Carus referred to Spinoza’s monism as henism (from hen to one) reproaching it in substantiality. Carus’ concern was to understand monism in a framework of religious historical development and he put forward the following scheme: polytheism – monotheism (implying an impulse against idolatry) – monism. Some scholars argued that polytheistic systems develop in the direction of monism rather than that of monotheism (Bianchi). Spiegelberg insists that historically religions were dualistic and only as a result of development, they were mitigated or even substituted with monistic or mystic explanations. Indeed, monism is welcomed in the guise of mystic in religions like Christianity, Judaism, and Islam. Anti-monistic groups also arose to counter the threat posed to traditional religion, most notably the Kepler-Society (Keplerbund 1907). They attempted to provide an alternative religiously and ethically determined worldview based on scientific knowledge.

It was the mind-body identity theory that monism postulated against Cartesian dualism. Though mental and physical terms differ semantically, they refer to the same objects or tokens. This approach was criticized for reductionism in the early 1970s. Recently Davidson (1995) offered theory which is the most influential and lively discussed today and put forward the so-called anomalous monism argument of identity between mental and physical event tokens. The same event according to him might be described in physical and mental terms. The asymmetry of the physical and the mental nevertheless remains since solely physical events are postulated to be of fundamental kind. It is not the question of every physical event being a mental one. Anomalous monism theory did not share the assumption about predictability of mental events on the basis of the knowledge of physical laws and using terms of physical description: Mental events do not fall under physical laws and are unpredictable, i.e., the mental is an anomaly and there are no strict psychological and

psychophysical laws due to the fact that Psychology like Biology is not a closed Theory. Though the relation between mental and physical is here law-like, this relation allows for anomalies as well. The issue is not about predictability of mental events in mental terms within the framework of this theory which would be of outmost interest for the relationship between science and religion connection. This theory itself does not take the issue off the table however. Dualistic remnants are still there in the view that some mental predicates (including propositional attitudes concerning belief) cannot be reduced to physical predicates. Cartesian interactionists would anyway insist that a comprehensive theory (aimed at description and explanation) should include physical and mental terms because what the latter designate might be force-generating properties and therefore indispensable for any comprehensive theory of the world. The argument for monism is that should there be many existences, relations between them would have to be reaching to infinite regress. The argument against this argument was that relations are not things and are not subject to this dilemma.

A special problem is the relationship between monotheism (see ► [Monotheism](#)) and monism. Given the problems of historical monotheism endowed with polytheistic impulses, philosophical monism sometimes was regarded as more consistent than the former and even truly philosophical monotheism. Another problem is the relationship between pantheism (see ► [Panentheism](#)) and monism. While some scholars argue for identity of pantheism and monism (H. P. Owen), others defend the view that they may be (Spinoza) but should not necessarily be identical (M. P. Levine). Pantheism more often than not proves to be pluralism and not monism.

Ernst Mach converted to neutral monism that was a perception-based phenomenalist monism. Together with Russell and James, he held that the mental and the physical are different aspects of a single stuff that in itself is neither mental nor physical. While acknowledging “neutral elements” which in some relations belong to psychical experience, but in others to physical world, he

tried to dissolve the problem of dualism inherited from Descartes. Ontological dualism of Self and the World was supplemented through epistemological dualism of the inner experience, given to the subject with immediate certainty, and knowledge about the outer world, uncertain and unfounded. Whereas the existence of the outer world could be open to question, the fundamental attitude of this subject has become the attitude of cognition. Idealist monism sees material bodies as a way of speaking about mental states. Material monism acknowledges that there are only material existences and reduces everything mental to the facts about matter. The Christian philosophers do currently take the materialist challenge seriously and try to integrate the materialistic line of thought into the Christian understanding of reality and history (incarnation, afterlife). The encounter with materialist monists on those conditions seems to be possible. Dualistic overtones can be mitigated by dialectics and therefore cannot help involving monistic speculations. This might be seen in Marxism and other varieties of dialectical thought with dualistic assumptions.

The attacks from pluralists were challenging and stimulating the proponents of monism as well. Since the paramount task in contemporary philosophy as seen by phenomenologists is to solve the problems stemming from the ontological dualism of Cartesian and neo-Cartesian provenience having negative logical (interaction) and historical (evolution) consequences, the phenomenological ontology is offered as one possible solution of this problem. A. Lovejoy presented his own theory of monism and dualism. He called monism, especially epistemological monism primitivistic. The ontological monism of Bruno and Spinoza, as well as later on monisms of F. H. Bradley and Bergson came under heavy fire. Lovejoy has combined both pluralistic metaphysics and dualistic epistemology. Epistemological monism holds that there is only one set of truths which are valid. Pluralism stating that conflicting or incommensurable views may be equally true is at best appropriate to use it for substantiating polytheism in the modern sense of this term (see ► [Polytheism](#)). Epistemological

pluralism might have important consequences for the whole philosophy of science. The most zealous attacks against monism came from the camp of logical atomism. Russell's theory of logical atomism triggered the development of analytical Philosophy; it was formulated against the monistic teaching of Britain absolute idealism, inspired by Hegel's logic, which held that there is only one indivisible substance. Against it was set a logic that acknowledges many independent things (particulars) which are independent of each other and not causally interrelated. It is logical atomism in the guise of pluralism. It has been held that Wittgenstein's *Tractatus Logico-Philosophicus* at best characterizes this view. This case appears to be more complex than presumed. The usage of monistic vocabulary is indispensable for a fruitful religious dialogue today.

[Personal God](#)

Description

Monotheism is a religious belief which acknowledges one transcendent and personal God who is distinct from the world and superior to it. One may believe that there exists only one God and reject the existence of other gods (exclusive or prophetic monotheism). One may believe that there are many gods but accept that only worship of one God is appropriate and legitimate (different terms like relative monotheism, potential monotheism (F.W.J.Schelling, Schelling 1927), or insular monotheism (Adrianus van Selms, Van Selms 1973) are used to describe this kind of monotheism) (Van Selms 1973; Schelling 1927). The notion of monotheism is closely related to the notion of the Supreme Being, which was developed in the eighteenth century religious studies and emphasized the ability of primitive/preliterate peoples to construe one single God. Monotheism is a controversial notion used for theological, ideological, and metaphorical goals. It has to be distinguished from Henotheism (notion introduced by Max Mueller as

a result of his Indian studies), which designates worship of one God for a relatively short time and by small communities or of rather insignificant local deities endowed for that period of time with the highest and worthiest attributes (Hornung in regard to Egypt, see: ► [Polytheism](#)). Monotheism is unattested in Greece before the Biblical time although there was a proposal to count Xenophanes “one greatest god” in Fr. 23 as an assertion of monotheism. Judaism, Islam, and Christianity are usually regarded as classical monotheistic religions. While it has not so far been questioned for Judaism until recent times (see below) and for Islam, it was subjected to doubt in case of Christianity, either by pagan authors (Celsus, Porphyrius, Maximus of Madaura), or by Jewish (and Muslim) authors. While their argument was primarily directed against Christian Trinity, European Enlightenment accused Christianity of polytheistic attitudes in its adoration of saints and angels (David Hume, Ernst Gibbon, Ernest Renan, Friedrich Engels, Adolf von Harnack and Eduard Meyer, Schopenhauer). Christian apologists defended Trinity saying that the unity of divine person can be grasped with the help of notions like homoousios (consubstantialis, co-substantial) and perichoresis (circuminssio, mutual penetration) of three hypostases. Angels were declared to be subordinated to One God and no divine beings with autonomous will. Apologetics with regard to Virgin Mary was more complicated but it is not our concern here.

In Judaism can be found a classical definition of monotheism in the Book of Deuteronomy: “Hear, O Israel, the Lord our God, the Lord is one” (Dt. 6,4). The Jewish philosopher Maimonides comments on this passage: “I believe with complete faith that the Creator – blessed be his Name – is One and Alone; that there is no oneness in any way like Him; and that He alone is our God – was, is and will be.” Christians express this with the words of Paul in 1 Cor. 8:4: “We know that an idol is nothing at all in the world and that there is no God but one.” Quran, Sura 5, 73 states: “There is no god except the one god.”

The most widely debated questions on and around monotheism in the last 150 years have been: Is monotheism the result of some

developments or is it an original phenomenon? Is monotheism a normative or a descriptive notion or both? Does any real monotheism exist at all or is it no more than an idea or ideal? How many monotheisms are there? Is monotheism – given its transcendent orientation – friendly to the nature? Is monotheism tolerant to other religions or are monotheisms tolerant to each other (if there are many of them)? Is monotheism “democratic?” Many of these questions are very complex. The debates are hardly understandable without recourse to such notions as Polytheism, Pantheism, Monism, and Panentheism.

There are two competing views on the origins of monotheism. One type of theory stresses that monotheism is a result of a long religious development, a late and high level of it. The other type insists that monotheism is an original and very authentic form of religious experience representing a kind of natural truth. Sixteenth century deists (Herbert of Churbery, Voltaire, Lessing) and Catholic missionaries preferred the latter view. It was heavily criticized by Ethnologists who found the notion of Monotheism inappropriate for primitive religions (existing in small-scale, preliterate societies), too abstract and implying hierarchic evaluations which in those societies do not exist. There are nevertheless monotheistic traits in some primitive religions (Nuer). The evolutionary treatment of monotheism was criticized as well. Both theory types would now and then return in a somewhat different setting in different phases of historical and theological development. Pettazzoni suggested using the term of Supreme Being in case of primitive religions not to be confused with God of Monotheism (Pettazzoni 1955, 1956). Nevertheless much of the contemporary research runs against this warning. An attempt has been made to reconcile the evolutionary perspective with the original one and to relate the “Supreme Being” (exchangeable with the “high god”) to the “God of monotheism” in order not to abandon the evolutionary picture altogether. North American cross-cultural and empirically tested research since the 1960s (leading scholars: Guy Swanson, Robert Underhill, William Irons) asked after the preconditions of monotheism,

operating with the notion of “high god” that is presumed to be the sole creator of the universe and that rules the world and heavens. This representation was detected even in preliterate societies. Five explanations were given. The presence of high gods can be related to the number of hierarchically organized sovereign groups a society possesses, a sovereign group being one that has an independent jurisdiction over a particular realm of social life. The high god is a personified being that represents a sovereign group’s desire to maintain order and diversity among subordinate sovereign groups. Swanson used a sample of 50 preliterate societies derived from the *World Ethnographic Sample* of 556 societies and in societies with four or more sovereign groups, 91% possessed a high god. This kind of questioning corroborated the view the classic French sociologist Emile Durkheim that monotheism is able to integrate economically and politically complex social structures. Davis found that as societies moved to higher technological stages and became more complex, belief in a high god not only became increasingly common, but high gods were progressively more perceived as being concerned with human morality. A high god was seen as morally active in only 9% of hunting and gathering societies but was perceived as active in 37% of simple and advanced horticultural societies and 67% of intensive agricultural societies. Underhill followed the Marxian line of argument that the economic base and productive forces of a society are the primary determinants of the superstructure, and religion, as part of the superstructure, is a reflection of the material conditions of social life. Underhill introduced independent and dependent variables. Monotheism was a dependent variable and was operationalized by noting whether a “high god” was present or absent in the sampled societies. The independent variables were the levels of economic and political complexity. Underhill found a strong positive relationship (zero-order, $\gamma = .63$) between Economic Complexity and Monotheism and a similarly strong positive relationship (zero-order, $\gamma = .56$) between Political Complexity and Monotheism. Simpson criticized

Underhill's Marxian presumptions and asked after other fundamental structures besides the distribution of power and authority upon which the belief in a high god may rest. He showed the relationship between high gods and the means of subsistence, for example, that "the extent to which subsistence raw materials are active or inert makes a significant contribution to explaining the presence of a high god. Active raw materials have instability, unpredictable resistance, or wide variation in those features that must be attended to in order to control the material. Conversely, inert materials are stable and exhibit predictable resistance and uniform properties that are easily controlled. Active raw materials present non-routine stimuli while inert materials project more routine patterns of attendant features. As a consequence, task performances associated with active materials tend to be fraught with uncertainties while responses to inert materials have a fixed programmatic quality." Simpson's argument extended dominant sovereign groups correlation with the presence of high god, elaborated by Swanson. "Both dominant sovereign groups and autonomous pragmatic individuals are associated with the presence of a high god because they both exemplify an acting unit carrying out its own purposes" (Simpson 1979). William Irons offered another "good Marxian" explanation that a moral high god emerges in stratified societies as a way to sedate the masses while preserving the privileges of powerful elites. Irons' hypothesis was discarded; Roes found but a weak correlation (Pearson $r = .24$) between class stratification and the presence of high gods. Richard Alexander proposed a very modern sounding explanation. As societies increase in their size they encounter new problems in terms of unifying very large numbers of people, and thus religion not only serves as a major means of this unification, but even does so in the form of moral rules. The Alexander hypothesis met with support. Sanderson and Roberts (2008) tested all five hypotheses directly against each other by means of multiple regression techniques. The high god variable was substituted by the stage of Religious evolution variable. The mode of subsistence

economy (active-passive raw materials), writing and record keeping, and total population size were responsible for each higher stage of religious evolution, including the presence of high gods. The sovereign group hypothesis became a weak support. Sanderson (2008) suggested that the new religious doctrines emerged to deal with the heightened sense of ontological insecurity produced by major increases in the highly disruptive consequences of rapid urbanization and intensified warfare.

Other research strategies were developed in studying Jewish monotheism. Robert Karl Gnuse explored the emergence of Israelite monotheism out of Canaanite religion ("emergent monotheism"): "monotheism developed over the course of many centuries. . . and these developmental stages often come in 'bursts' in response to particular social and religious crises" (Gnuse 1997). Gnuse understands Israelite monotheism as developing throughout the first six centuries of Israel's history and as coming to full expression only in response to the social and religious crisis of the exile. Most of the biblical scholars who discuss the emergence of monotheism are favoring an evolutionary model that culminates with a full-blown expression of monotheism in the exilic period. This evolutionary model can be improved on through the notion of "chain of revolutions," that is, a chain of rapidly following each other successive revolutions in the direction of monotheism (Lang), pushed forward by "prophetic minority" (e.g., the revolt of Elijah, Elisha, and Jehu, the reforms of Josiah, and the crisis of exile). Rainer Albertz, Othmar Keel, Bernhard Lang, Mark S. Smith, and Robert Karl Gnuse hold this view. There are theological implications of an emergent model of monotheism. An evolutionary model with relation to monotheism allows us to look upon the biblical faith as still evolving and consequently allows us to reject some of that faith's outmoded conceptions, such as its patriarchal bias. Even if one like Albright holds the view that monotheism appeared in Israel early, biblical faith taken more generally could still be described as a tradition in process. Indeed, Gnuse works out his theology of "process." This research strategy

finds its complement in an attempt to locate the development of Israelite monotheism within the larger intellectual climate of the ancient world. He especially concentrates on the emergence of Vedic monism in India, which he refers to as “pseudo-monotheism,” in Zoroastrianism, and of the more than “monotheistic intuitions” of Xenophon of Colophon and other pre-Socratics, all of which occurred at roughly the same time that many scholars have called the “Axial Age.” Nevertheless, according to him, monotheism reached its full expression in Israel. Gnuse further argues that these simultaneous points of “intellectual breakthrough or transformation” might well be described using the biological model of “Punctuated Equilibria,” whereby “small mutations over a long period of time are stored as recessive genes in the matrix of a species, and at some point they emerge in tandem . . . to produce an evolutionary breakthrough” (Gnuse 1997). “In effect, the ancient world was creating mutations which would lead to breakthroughs in several places . . . [including] the monotheistic breakthrough of the Jews or the Jews and their contemporaries” (Gnuse 1997). To be sure, the application of a scientific model to the field of cultural history is methodologically controversial.

The attempt to extend the notion of monotheism on other high cultures of the Far East has parallel development in stressing the impact and role of “philosophical monotheism” in Western thought and civilization. Sometimes, gods are seen as members of one God (*membra*, Maximus of Madaura, Letter 16, PL 33, 82). The notion is closely related to that of philosophical (natural) Theology, favored by Varro and Posidonius, contrasted to civil and popular Mythology. Lang holds that philosophical monotheism is inclusive in relation to popular polytheism (see ► [Polytheism](#)).

Monotheism had deep roots in the Mediterranean world. Some classical scholars argued against the opinion that belief in one God was the exclusive preserve of a Judaeo-Christian tradition (orthodox or heretical), isolated from the classical world which surrounded and enveloped it (Frede) (Athanassiadi and Frede

1999). M. L. West examined monotheistic thinking in early Mesopotamian, Hebrew, and Greek (down to Xenophon’s *Memorabilia*) religions (monotheism was mingled with polytheism here, although the extent to which monotheism came to the fore varied); John Dillon in the various monistic forms of Gnosticism (Gnosticism presents us with a monistic system where the first principle has no countervailing entity not of his own making. This principle is far more transcendent and impersonal than the Jewish or Christian God); and Wolf Liebeschuetz develops syncretic arguments for a Supreme Deity advanced by Praetextatus in Macrobius’ *Saturnalia* (and paradoxically states that the whole of ancestral religion was fundamentally monotheistic). Frede concludes that “not only philosophers, but a very substantial portion of late antique pagans was consciously monotheistic” (Athanassiadi and Frede 1999) and the gap between pagan spirituality and Christian faith was not decisive. There are substantial continuities that connect monotheist thought after Constantine with much preceding religious practice and theological speculation. The pagans in late antiquity came to adhere to different forms of monotheism, which ultimately enabled them to accept Christianity. Lautner, Bowersock, Fowden, and J.P. Kenney showed that with its monotheistic tendencies, Platonism in the imperial age decisively contributed to the process of assimilating Judeo-Christian and pagan traditions.

Even the exegesis of the late second century Chaldaean Oracles by some neo-Platonists (Proclus, Damascius) shows that, despite differences between them, neo-Platonists tend to explicate these sacred texts in monotheistic terms although the texts themselves may be expressions of polytheist theology. This tendency may be accounted for by a variety of explanations. There was a long-term internal process of elaboration going on, or possibly the monotheistic “spiritual globalization” of the ancient world was the result of a series of convergences and overlaps between long-standing monotheistic theologies and Christianity. These may also have been important factors in provoking “sharper contours and a clearer definition to

polytheistic belief” (Athanassiadi and Frede 1999), as well as a growing sense among polytheists of “themselves as a group with a common cultural past and a common interest” (Athanassiadi and Frede 1999).

Christian Theology found a bridge between philosophical and Christian monotheism and the same may be said about deism, which asserts that philosophical faith in God is a natural religion and does not require any revelation (Herbert of Cherbury). David Hume distinguished between the aspiration of philosophically thinking elite to grasp the world as unified (that is rather monism) and popular monotheism using monotheistic dispositive for more effective achievement of its goals.

Paul Radin emphasized that monotheistically thinking individuals are everywhere likely to occur with a certain frequency – in all societies regardless of its stage of development because monotheistic conceptions are rooted not in a distinctive form of civilization but in a peculiar type of temperament. We must – according to Radin – expect to find monotheism as on obligatory faith at every cultural level. It is the devout – as opposed to the intermittently religious – temperament that must be credited with monotheism.

Sometimes, the Supreme Being is seen as failed evolution, where the differentiation of deities has not been carried out yet: every important function is ascribed to one divinity (Gladigow). The evolutionary picture should not be completely given up in this case, only the Supreme Being does not fit in the picture. Pettazzoni insisted (Pettazzoni 1955) that the evolution starts with a high all-seeing heavenly being of primitive religion, followed by the highest all-knowing heavenly God of polytheistic Pantheon, and reaches its highest stage in the unique and all-knowing God of monotheistic religions. Pettazzoni held that it is necessarily ambiguous. His theory seems to fit for Echnaton in the case of Egyptian monotheism, but it is hardly applicable to Judaism. The sun god, represented through the sun disc, was selected in Egypt for that construction of the highest God by Amenophis IV. God was named “sun of

righteousness” by Maleachi 3.20; Essenes worshipped the rising Sun. This suggested that the sun deity is predisposed for monotheistic constructions. On the other hand the problem of influences of one religion/monotheism upon another was also debated. Aton-Hymns were compared with Biblical tradition (Ps. 104). Egyptologists have not ruled out the influence of Echnaton on Judaism (Hornung). This influence was stressed by Freud in his famous *Moses and Monotheism* as well. Although lively discussions are being held about Freud’s work today, this hypothesis finds hardly any supporters within Judaism or Judaic studies (Assmann – Bernstein debate).

The critique of monotheism was prepared by David Hume, who emphasized intolerant traits in popular or institutionalized monotheism as well as inclination to passivity. Although this assertion is widely quoted today, another statement by Hume is almost forgotten, namely, that monotheism represents a more perfect religion and correlates with a higher educational standard of society and more elaborated and comprehensive thinking. Schopenhauer followed Hume’s footsteps in his critique of intolerance in monotheism and so did Nietzsche. Nietzsche objected to Christian monotheism being sterile in the mythological sense (Antichrist) and called for creativity as “a creation of new gods.” Even scholars who highly acclaimed monotheism in the evolutionary perspective, like Comte, charged it with antisocial dispositions: monotheism favors direct connection of individual being with God and ignores social structures. There is a line of extreme critique in modern scholarship (although it is not widely shared in scholarly communities) which links monotheism with patriarchalism, totalitarianism, monotonous character, and holds that monotheism is opposed to political pluralism. Regina Schwartz states that monotheism and all that it entails is responsible for a whole laundry list of Western civilization’s historical and modern sins: exclusivism, authoritarianism, intolerance, misogyny, ill treatment of minorities, jingoistic nationalism, fundamentalism, patriarchy, and, in general, violence toward the Other (Schwartz 1997). Using observations

about the relations of identity constructions and their religious validations, Schwartz wants to argue that it is “the myth of monotheism” that “grounds particular identity in universal transcendence”; it is specifically monotheism “that forges identity antithetically-against the Other.” The argument here is that monotheism entails “scarcity” in contrast to “plenitude,” at best – according to Schwartz – represented through polytheism. Schwartz defines “scarcity” as a sort of metaphysical principle that delimits all sorts of things: Monotheism presumes oneness – the oneness of God and the oneness of His favor and of His people. “[T]here can be no multiple allegiances, neither directed toward the deity nor, apparently, emanating from him.” She renames monotheism into a “myth of monotheism” that is depicted as “a system in which identity depends upon rejection of the Other and subjection of the Self.” Schwartz establishes a difference between “bad” monotheism and “good” monotheism: “bad” monotheism is particularistic, exclusive, and bound up in the metaphysics of scarcity and the violence accompanying it; “good” monotheism is universalistic, inclusive, embraces the principle of infinite bounty, and is presumed to steer humans away from violence. “The logic of negation should be distinguished from one of multiplicity, a logic that sustains contraries without obliteration that multiplies differences” (Schwartz 1997). The principle of plenitude contains an “infinite potential.” Schwartz points to a few biblical narratives and passages where God is depicted operating under the “ideal of plenitude” and wants to define those as politically correct monotheism, a theology for the postmodern age (*Exod. 16:15-18*). But even good monotheism can go bad: good, universalistic monotheism results all too often in imperialism. This Levinasian line of critique taken up in Schwartz’s conception and originally (in Levinas) rooted in his understanding of monotheism is directed here against monotheism itself in order to rule it out, which detects a heavy misunderstanding of relationship between monotheism and otherness.

Rodney Stark speaks of inherent logic of monotheism. The God with the greatest scope

and power is, by definition, the best, so having One True God will always trump lots of little limited gods. To be a “One True God,” you have to be personal, conscious, rational, responsive, and dependable according to rational belief theory, favored by Stark, so that people can develop a relationship with you over time. Others with competing One True Gods will be reluctant to change, but those with weak gods will be easiest to convert. Unfortunately, competition between monotheisms always results in contempt for the other. Monotheisms will missionize, will fight each other, and can survive in hostile circumstances. This logic of monotheism is what allows Stark to argue that Hinduism despite its apparent polytheism, is essentially monotheist, because they are effective missionizers.

Richard Niebuhr puts forward the notion of “radical monotheism” that evoked debates in the North American space (Niebuhr 1943). He stated that the mind of man is a perpetual factory of idols. “Radical monotheism” is monotheism taken with utmost seriousness. Nevertheless, it has nothing to do with morality. He objects to modern moralism that it “has subordinated all other value categories to those of the morally good and morally bad.” Science and art have more or less successfully resisted the tyranny of moralism but religion has accepted the yoke willingly and allowed its concept of sin to be reduced to “moral guilt.” Monotheism is seen as a contrast term to “Henotheism” or social faith, the term that describes the beliefs resulting from the fact that finite tends to elevate some finite thing to the place of God, as an object of loyalty and trust (which makes a finite society, whether cultural or religious, the object of trust as well as of loyalty and which tends to subvert even officially monotheistic institutions, such as churches). In henotheism, there is worship of one God among many, not of one supreme God above all. Niebuhr asserts that human nature is sinful and idolatrous but not morally bad; sinfulness is disloyalty to the true God, to the only trustworthy and wholly lovable reality, which implies a false loyalty to something that is not God but which claims deity. “Idolatry leads inevitably to polytheism and polytheism is conflict” (Niebuhr 1943) Man’s common life and culture are at war with

monotheism. Radical monotheism finds its center of loyalty only in the principle of being itself, only in a loyalty to that One Reality by which all other realities exist and in which they participate. When Western man is not henotheistic, he is likely to be polytheistic (see ► [Polytheism](#)), thereby losing even the limited unity which henotheism (strong identification with national or state values) affords. Scholars like Zizek (transcendental materialism), Catholic authors like John Courtney Murray and many Protestants alike saw reliance on human orders as dangerous and involving one or other form or variety of paganism or idolatry.

Protestant Theologian Paul Tillich opposed monotheism to idolatry by stressing the idolatrous identification of the ground of our being with the God of ordinary theism. Idolatry meant for him the magical identification of the Divine with the bearer of the Divine. The representatives of Theism, like William Alston, indicated that this definition is vitiated by difficulties. Symbols always have a tendency to replace that to which they are supposed to point, but it is impossible for the ground of the being. The holiness of the things may perhaps be considered as inherently holy in the case of idolatry. But if their holiness is inherent and not defined through reference to deity, how can they be holy (and “idolatrous” as a kind of perversion in treating the holy matters) at all? The difficulty lies in the fact that we could frame a possibility that the very place of being has been taken by something else only if “symbolize” (and “ultimately concerned with”), on the one hand, and “being itself,” on the other, had already been defined independently of each other, which is not the case here (W.P. Alston).

There are scholars and rabbis who maintained the compatibility of the Jewish tradition, including monotheism, with pluralism. The Chief Rabbi of England Jonathan Sacks suggests that all monotheistic religions revise their religions explicitly. Sacks makes this (self-)required revision in the form of an additional constitutional amendment to Jewish monotheism stating that the one God, creator of diversity, commands us to honor his creation by respecting diversity. He invites each faith to word this statement (formulated in the Jewish language) in its own termini. It is

formulated in one particular language and at the same time it has a universal meaning as a statement in a meta-language. “God is the God of all humanity, but between Babel and the end of days no single faith is the faith of all humanity.” Jewish critics argued that it is incompatible with Jewish belief (“The Revelation at Sinai was a unique event and never to be repeated in history,” Jonathan Rosenblum). In any religion, traditionalists consider that their scripture alone is the voice of the living God (that is called triumphalism, and supersessionism), which is sure to cause problems. Hilary Putnam maintains that the claims to infallibility always conflict and even the claims to infallibility made by one single religious community always conflict with themselves, which may lead to horrible consequences. Putnam expects that some people will be willing to accept this “amendment,” but not the majority in the foreseeable future. His call echoes Sacks’ plea: each of the religions should find resources within its own texts to support the idea that God values diversity. Reference of epistemologists to the “privileged access to the truth” should be discarded in the case of religion. Any religious tradition and institution is fallible; no one possesses an epistemic authority. A middle way has to be found between the skeptical antireligious view according to which religions should be replaced by some other source of enlightenment, and the view that religion is the final view, time and again ascribed to monotheism. The love of God and the love of one’s fellow beings have at times been treated as if they could be in conflict (Putnam 2006). For Putnam, it is the inconsistency of any human institution in its ideology and working which generates it (this remark reiterates the statements already expressed by Schopenhauer in *Parerga*). Putnam suggests—reiterating Kierkegaard and Wittgenstein—taking a critical stance toward the notion of “superstition” (a counterpart notion for idolatry) as an improper way of embracing the religious truth, as a wrong *kind* to be religious; religion cannot be deduced scientifically. The words said, however “true,” may not suffice to show that one is religious, or that one is worshipping God and not an idol. This allows Putnam to speculate that if it were so that Jews

and other monotheists always lived up to *their* values, while “idolators” only professed to do so, the monotheism – idolatry opposition in relation to monotheistic and non-monotheistic religions might still work. Hence, representatives of other religions expressed critique of their institutions and practices, which shows that there are inner resources in almost each culture to criticize itself. That explains why both Sacks and Putnam are ready to add to monotheistic religions not only Judaism, Christianity, and Islam, but also Hinduism, Buddhism, Taoism, and Confucianism as self-improving religions, a statement that might echo Martin Walzer’s concept of self-improving communities.

Jewish scholar and Rabbi David Novak countered the above-mentioned objection to monotheism by laying emphasis on the concept of a transhistorical redemption, which makes room for true tolerance and a more sophisticated universalism that allows for a wider variety of human responses to the divine presence. Novak distinguishes between “common monotheism” that promotes international relations and the “historical revelation” that makes possible a “truly unified community.” He insists on leaving redemption to God rather than expecting it as the result of human efforts that allows for a greater openness to religious variety and particularity in the present age. Transcultural covenants between different communities are possible in his view only between monotheists. A kind of universal monoculture of humanity is not possible altogether (Novak 2005).

Some uneasiness with “monotheism” can be detected even in the Jewish scholarship since the 1970s. This term is beginning to be used more cautiously. It has been said that the term is not appropriate to describe the Jewish idea of God, that no progress beyond the simple formulas of the Book of Deuteronomy can be discerned in Judaism before the philosophers of the Middle Ages (who performed massive allegorization of the tradition), and that Judaism is hardly likely to escape from the legacy of the battles for supremacy between Yahweh, Ba’al, and El from which it emerged. The opinion was heavily challenged that the experience of mystical unity with God is missing in Judaism because it is incompatible with

Jewish definitions of monotheism. Sometimes scholars see no difference between the range and scope of rabbinic polemic against the angels and the prophetic polemic in the Old Testament against the worship of other gods. The rabbis even had to ban the making of images of angels and other heavenly creatures, as well as the practice of sacrificing to angels, especially to archangel Michael. The existence of such practices testifies to the fact that lots of Jews had continued the old Israelite pagan practices and substituted the angels for the Canaanite gods, similar to the minor nature divinities of the Greek pantheon and the nature spirits ubiquitous in all human societies. Jewish angelology shows that the Second Temple and rabbinic periods are characterized by moving away from the monotheism which is more closely attained in the Book of Deuteronomy. Some scholars explain the apparent proliferation of belief in angels in the post-exilic period as a reaction to the distancing of God from Israel consequent upon the adoption of a transcendental monotheism. Corbin maintained that monotheism is not possible without angels altogether and called this a paradox of monotheism. Another explanation was that Deuteronomy stands apart from the mainstream of Israelite and Jewish beliefs and witnesses to the views of a small coterie of priests and scribes, the group to which Morton Smith gave a name “The Yahweh Alone Party” (Smith 1987). Whatever would be the term that seems more appropriate than monotheism – “a cooperative dualism,” the belief in “two powers in heaven,” multiplied in patterns like Yahweh – Michael (or Yehoel or Metatron, or Melchizedek), God – Logos (Philo), God – Shekinah or the Sefirot, God – Active Intellect (medieval Philosophy), till the Attribute of Justice and the Attribute of Mercy of God (rabbinic literature), supreme God and the demiurge (Hellenistic Judaism, see ► [Gnosticism](#)), and many others, the very notion of monotheism has to be clarified in a more sophisticated manner. Raphael Patai responded to this challenge by distinguishing the popular from the high doctrinal level. Middle Eastern religions are polytheo-demonistic at the popular level and monotheistic at the higher doctrinary level; Western religions in their turn are polytheo-demonistic at the

folk-cultural level, indifferently monotheistic at the modern popular level, and exclusively monotheistic at the official religious level. There are other clarifications of this state of affairs. David Novak claims that monotheism was predominant in Israel from its very beginnings and idolatrous distortions like worship of minor deities were seen as being compatible with the worship of the one God. Post-exilic prophets like Maleachi (1:11–12) state that Jewish worship to Him is inferior to that of some other nations, which allows us to look back at philosophical monotheism. Even the existence of the above-mentioned aberrations may be regarded as the reason for rabbinic teaching that polytheism is prohibited universally (with reference to Talmud, Avodah zarah 8.4 and B.Sanhedrin 56 a-b).

Some uneasiness can be observed in the use of the notion of ethical monotheism as well. This term was introduced by Protestant theologian Abraham Kuenen in 1877, taken over by Julius Wellhausen in 1894, and especially favored by German Jewish philosopher Hermann Cohen. It meant that the only God is righteous and demands ethical behavior on the part of Man. It further implied that the mission of Judaism and the Jewish people is to teach ethical monotheism to the world until the world is fully ready to accept and practice it. Cohen's approach and reaction to it can at best indicate the tension between philosophical monotheism and monotheism as a historically particular revelation to one particular people or community. North American neoorthodoxy (Richard Niebuhr) rejected the notion of ethical monotheism as well. The faith is to be understood more widely than one separate branch of human behavior (ethics). It was favored by liberal theologians in Europe and North America. The debate is still going on.

The term "ethical monotheism" has sometimes been applied to Zoroaster. At the existing level of (rather insufficient) clarification of the term "ethical monotheism" it appears rather unusual to employ it actively. This can be said about the term "monotheism" more generally as well.

Ecoteology (Lynn White) believes that environmental crisis can be overcome only through return to pagan or Asia's religions – there have

been only a few Christian counterparts like St. Francis of Assisi who offered alternative "eco-friendly" religious attitudes. The answer of Christian Theologians is as follows: Darwinian laws of jungle do not prescribe protection of other species. Only Biblical message (especially the statement on man as image of God) is responsible and capable to do this protecting. There is virtual self-contradiction in play: man has to look to the nature for the values of right behavior but is instructed to behave by a standard found nowhere else in nature. This standard cannot be established even by science, which regards man as subjected to the same laws of nature. It was stressed that dominion demand in Genesis 1 has to be seen in juxtaposition to the care demand in Genesis 2, and Ps. 8 and 24, as delegated dominion that involves Biblical model of human stewardship.

Moore's Law

Robert M. Geraci
Associate Professor of Religious Studies,
Manhattan College, Riverdale, NY, USA

First described by Gordon Moore of Intel in 1965, Moore's law has been variously defined (over the years) to state that the number of transistors on an integrated circuit doubles every year, 2 years, or 18 months. As computer speed doubles with the doubling of transistors, this indicates that progress in computational speeds has been, for several decades, exponential. Some roboticists and AI theorists believe that Moore's law will continue unabated, providing near limitless computation and, eventually, transcendently intelligent machines.

Movement Disorders

Lars Wojtecki and Alfons Schnitzler
Department of Neurology, Institute of Clinical Neuroscience and Medical Psychology,
Heinrich-Heine University, Duesseldorf,
Germany

Description

Movement disorders delineate a subdiscipline of *neurology* and are caused by affections of the central nervous system (with is composed of the brain and spinal cord. Your brain and spinal cord

serve as the main “processing center” for the entire nervous system, and control all the workings of your body). Movement disorders comprise a group of neurological conditions that are characterized by problems with movement – either unwanted movements or slowness and poverty of voluntary movement – which are a subject of diagnosis, therapy, and research. Within the central nervous system especially deep brain structures, the ► [basal ganglia](#), and their interactions with other brain areas are involved in the *pathophysiology* of movement disorders. Early descriptions of illnesses associated with alteration of movements as well as the anatomical distinction of cortical and subcortical brain areas go back to the Middle Ages. Systematic studies on disease entities and their pathological correlates have been published since the nineteenth century. In the 1980s, an international organization ([The Movement Disorder Society](#)) was founded and today movement disorders are an expanding discipline of clinical and experimental *neuroscience* and treatment by means of *pharmacology*, *neurosurgery*, and *physiotherapy*.

Self-identification

Science

Movement disorders as a speciality developed within the disciplines *medicine* and *neurology*. The discipline identifies itself as a *natural, life and human science*. On the basis of description and classification of movement *phenomenology* different clinical syndromes are distinguished. The discipline aims to provide knowledge about *etiology*, *pathology*, and *pathophysiology* of different diseases by discovering structural and functional changes of the nervous system. Scientific methods are applied to establish an objective basis for specific curative or symptomatic therapy. Methods of all disciplines of *neurosciences* are accessed for research such as *neurophysiology*, *neuroanatomy*, *neuropathology*, *neurochemistry*, *neurosonology*, *neuroimaging*, *neuropsychology*, *neuroradiology*, and *molecular neurobiology*. Using this scientific background, evidence-based therapeutic regimes

Movement Disorders, Fig. 1 Early medical photography illustrating the movement disorder athetosis (Extracted from Bourneville and Regnard 1878). Conserved at and permission granted for reproduction by: Bibliothèque Charcot (UPMC-Université Pierre et Marie Curie) – Hôpital de la Salpêtrière)

in the fields of *neuropharmacology* and *functional neurosurgery* have been developed from movement disorders.

Characteristics

Accrued from *neurology*, movement disorders also refer to affections in functional nervous systems and disease-induced impairments of neurological functions. But different from other fields of neurology, movement is in the focus of interest. Accordingly, special scientific methods for movement analysis have been developed from the field of *electrophysiology* and *neurophysiology*. Additionally, *medical art*, *photography*, and *videography* have always played a key role in the documentation of movement disorders ([Fig. 1](#)).

Distinctive from general *neurology* is the fact that especially involuntary, automatic, and stereotyped aspects of motion are analyzed. According to a hierarchic concept, movement disorders give insight into basic aspects of motor parameters (e.g., rhythm, speed, duration, topography), which have to be distinguished from higher-order programs of movement planning. Since these automatic executions of motor plans are mainly attributed to subcortical structures like the basal ganglia, movement disorders focus on this distinct brain area.

As *sensation, cognition, emotion*, and especially *affective gesture* and *mimic (psychomotoric)* can also be altered in movement disorders, this discipline also deals with stereotype and automated subconscious aspects of these functions and its relevance from basal ganglia interactions with other brain areas. Accordingly, the discipline movement disorders is related to *neuropsychology* and *psychiatry*.

Relevance to Science and Religion

Movement disorders are a domain among *clinical neuroscience*, which uses input from and also provides input to all other neurosciences. With some of its specific methodological approaches, such as invasive electrophysiological neuronal recordings during *functional neurosurgery*, it can contribute to a deeper understanding of brain *physiology* and especially involuntary, subconscious control of behavior within the discourse of *neurosciences* and *humanities*.

Sources of Authority

The history of movement disorders is strongly associated with the first systematic reports of typical disorders, which still bear the name of their first descriptor. In 1686 Thomas Sydenham published a report on a typical movement disorder with increased involuntary movements (hyperkinesia): the so-called chorea minor, which today is still known as “Sydenham Chorea.” James Parkinson wrote his “Essay on

the Shaking Palsy” in 1817 describing a disease, which is up to now called “Parkinson’s Disease” (Parkinson 1817). Besides its clinical presentation with tremor this disease is still the most exemplary form of a movement disorder with decreased movements (hypokinesia). The description of these diseases marked the dualistic concept of movement disorders with hyperkinesia and hypokinesia at opposite ends. Focusing on Parkinson’s disease and other tremorous conditions, Jean-Martin Charcot (1825–1893) made fundamental contributions to the correlation of clinical syndromes with brain *anatomy* by means of regular autopsy. He also developed diagnostic methods to differentiate movement types and made basic considerations for pharmacological treatments. The term “basal ganglia” first appeared in English with David Ferrier’s writing of 1876 adopted from the German term “Stammganglion” coined by August Forel in 1872. William Hammond, William Osler, George Huntington, George Gilles de la Tourette, Hermann Oppenheim, Cecile and Oskar Vogt, Constantin von Economo, and S. A. Kinnier Wilson were seminal figures of the nineteenth and early twentieth century regarding pathological and clinical description of different movement disorders. One of the most central authorities in movement disorders of the late twentieth century was C. David Marsden (1938–1998) who combined *neuropsychology*, *neurophysiology*, and *neuropathology* in this field and established an international respected laboratory at the Institute of Neurology, Queen Square, University of London. He was also a founding member of the Movement Disorder Society, which today is the central international society of specialists and authorities in this domain ([The Movement Disorder Society](#)). Marsden, Mahlon R. DeLong, and Garret E. Alexander established the today widely accepted anatomical and physiological model on the functioning of the basal ganglia. With respect to therapy of movement disorders, the introduction of levodopa in the 1960s by André Barbeau, Walter Birkmeyer, and Oleh Hornykiewicz represents a milestone in the pharmacological treatment of parkinsonian

Movement Disorders, Fig. 2 Anatomical view into the human brain. Neurons of the basal ganglia, the cerebellum, and cerebral cortex are highly connected through pathways of the white matter. Functional changes of the basal ganglia can lead to movement disorders and can be modulated by drugs and electrical stimulation. Pathological examinations of as well as electrical recordings from these structures have a major impact on movement disorders research (From Putz/Pabst 2006; Permission granted for reproduction by Elsevier)

syndromes by replacing the deficient neurotransmitter dopamine. Based on topical models of the basal ganglia and stereotactic brain atlases established in the middle of the twentieth century by Jean Talairach and later by Georges Schaltenbrand and Waldemar Wahren treatment of movement disorders nowadays also experiences a renaissance of *functional and stereotactic neurosurgery*. Tracing back to early operations by Victor Horsley and Robert Henry Clarke in 1909, today movement disorders surgery mainly became a field of electrical ► **neuromodulation** by means of ► **deep brain stimulation** via implanted impulse generators introduced 1986 by Alim Louis Benabid and Pierre Pollak (Fig. 2).

Ethical Principles

Movement disorders as a medical discipline was historically guided by the oath and law of Hippocrates. Modern research is also based on the rules of the “Declaration of Helsinki” and its amendments by the World Medical Association.

This declaration is regarded as standard in medical ethics. Local and regional standards are discussed and regulated by institutional ethical committees.

Key Values

Movement disorders are devoted to increase the understanding of specific disorders and mechanisms of the respective brain subsystem to alleviate or even cure the underlying disease.

Conceptualization

Nature/World

Nature is everything of the physical world which is not originated by the human being. In *biology*, the term nature contains biotic forms – contrasted to abiotic nature – as animals, plants, and human beings. World is the totality of everything in the time- and space-defined universe that builds up reality and – in respect to biologic beings – their existence.

Human Being

The human being is a distinctive bipedal primate of the hominidae family equipped with a highly developed brain capable of *emotion, language, problem solving, introspection, abstract reasoning, intentionality, self-consciousness* and the knowledge of a *personal identity*. Movement disorders mainly focus on the treatment of human beings, although pathophysiological considerations are derived from animal models.

Life and Death

Life distinguishes organisms from nonliving objects (abiotic nature) by physical adaption and communication with the environment and especially self-regulation and replication. In complex biological systems with organ substructures, especially in the human body, life includes metabolism and functional states of the nervous system, which in a specific pathological state can induce movement disorders. Death is the final termination of biological functions. As the brain and its functional

state are considered to be correlated with human distinctive attributes like *personal identity*, brain-death is considered the death of the human being.

Reality

Physical reality is the objective true state of the world and includes everything whether or not comprehensible by beings.

Knowledge

Knowledge as possessed by humans is a justified, true, and believed statement about reality. Knowledge needs not to be conscious and can be the basis of biological dynamics and self-organization in biological systems. In medical disciplines like movement disorders, knowledge is intended to be produced by scientific methods.

Truth

Truth is the correspondence of belief with the objective fact of reality.

Perception

Perception is the *reception* and *awareness* and/or mental representation of reality by means of *sensation*.

Time

Time and space are the fundamental dimensions of the universe and human perception. Human perception of time can be affected by the focus of *attention* and impaired by diseases of the brain like movement disorders and also be modulated by therapy of these.

Consciousness

Consciousness is a mental state of a subject which is responsive to the outside world. Concerning *alertness*, it is quantitative. In human beings, it can also involve different qualities as *thoughts*, *sensations*, *perceptions*, *moods*, *emotions*, *dreams*, and *self-awareness*. Neurological diseases and movement disorders can alter states of consciousness. As automatic, nonvoluntary, sub-conscious movements are the focus of movement disorders, the definition of consciousness is a crucial point in this discipline.

Rationality/Reason

Rationality is a logical basis of organization of behavior, understanding reason as ultimate authority. Rationality can be altered in some movement disorders, and many involuntary movements are mainly executed without conscious reason.

Mystery

Mystery is a secret condition which seems not explainable by rationality and objective scientific methods. As movement disorders are nonrational behaviors, C. David Marsden provocatively pointed out “the mysterious motor functions of the basal ganglia” (Marsden 1982).

Relevant Themes

A critical issue in movement disorders in regard to science and religion is the definition of nonvoluntary movements. It raises the question concerning definitions of *free will*, *intention*, and *consciousness*.

M-Theory

Russell Stannard

Department of Physics and Astronomy,
Open University, Milton Keynes, UK

It is conjectured that there might exist a law of nature capable of spontaneously producing universes, including our known universe. It arises out of string theory – a theory based on the idea that the fundamental building blocks out of which everything is made consist of tiny vibrating strings. It is expected that the various universes spawned by M-theory would have different laws of nature and different values for the physical constants. There is as yet no evidence for this theory, and it has yet to be formulated.

Introduction

Muhammad, the Prophet of Islam, who received revelation from God contained in the Muslim

scripture, the Qur'an (Koran). Questions surrounding the life of Muhammad continue to puzzle some, but it is safe to ascertain that he was the source of inspiration for the development of Islam into a separate monotheistic religion in the seventh to tenth centuries CE and the establishment of many of its practical aspects. The traditional Muslim sources, such as *sira* (account of the life of Muhammad), collections of ► [hadiths](#) (reports about what the Prophet said or did, usually referred to as "traditions"), commentaries on the Qur'an, and works of history, describe the background of his life as that of the Arab pagan society which had little awareness of and connection with the established monotheistic traditions of the Near East of the seventh century CE. More recent scholarship, however, proposed to view the context of Muhammad's life as part of what is now termed as the Late Antiquity, a period of important religious, political, and social changes and fluidity in religious and intellectual life. The reason why we have such different pictures of the context of Muhammad's life is tied to the persistent problem of sources for the life of Muhammad. For this reason, any discussion about Muhammad inevitably involves description of the existing sources and why they cannot tell us much about the historical Muhammad.

The Problem of Sources

Sources on the life of Muhammad are many, but they all go back, at the earliest, to a century later than the events they describe. For a detailed description of sources on the life of Muhammad and overview of the earliest works, see Raven (2006). Also, see Rippin (1999, p. 455), Cook (1983, pp. 61–76), and Hawting (2005, 21–22). The earliest compilations of reports about Muhammad are those by Ibn Ishaq (d. 767), whose work we have in several later reductions, notably that of Ibn Hisham (d. 833), al-Waqidi (d. 822), Ibn Sa'd (d. 845), and al-Tabari (d. 923). Earlier sources do not exist in their original or complete forms and are extremely difficult to date. External to the Muslim tradition sources

(Hebrew, Syriac, Greek, or Armenian) are few, cannot be considered totally objective or disinterested. Moreover, their information is often at variance with the Muslim sources. The archeological and hard evidence (inscriptions, buildings, and coins), datable to the first decades of Islam, is also scarce and is inadequate for producing a historical picture of the period. It is, therefore, very difficult to talk about Muhammad outside the historical and religious context within which the Muslim tradition has firmly placed him.

Among the various genres of the Muslim historical and literary tradition, the bulk of which is written in Arabic, the *sira* literature in particular has always been viewed as the major source for the life story of Muhammad. Recent scholarship, however, showed that attempts to reconstruct the historical account of Muhammad's life from *sira* are futile. Instead, some scholars have increasingly concerned themselves with the new ways in which *sira* can be used to understand the concerns and preconceptions of the Muslim tradition about important issues of doctrine, theology, and authority (religious as well as political). Scholars who take this approach use *sira* works to understand the context within which they have been composed rather than that which they claim to portray.

Sira in its present form is a literary text and, as a result, the narrative and the image of main personalities of its stories developed in accordance with the conventions of a literary work. There are numerous versions of *siras* produced by many Muslim authors living in different historical, political, and intellectual milieu. *Sira* as a life story of Muhammad served many tasks. In particular, it helped to build his image in rivalry to other prophets, established his status as a statesman, provided context and a chronological framework for the Qur'anic text, reflected concerns of Muslim scholars with the early history of Islam, continued the ancient Arab tradition of storytelling, and addressed concerns of a didactic and legal nature by setting standards for the newly emerged community.

The Qur'an, also considered an important source for the life of Muhammad, contains very few direct references to Muhammad himself. His name is mentioned only four times in the Qur'an

(3:144, 33:40, 47:2, and 48:29). Moreover, the Qur'an does not provide any overall context for the early history of Islam or some of its most important doctrinal and theological aspects. It scarcely mentions personal or geographical names. It is allusive and fragmentary in nature. Therefore, almost every Qur'anic verse gives way to several possible interpretations, which is often skillfully used by scholars of various generations and persuasions to argue for their own case. On the one hand, the Qur'an is accepted as an important source for the life of Muhammad. On the other hand, the life of Muhammad is meant to provide a contextual framework for the understanding of the Qur'anic text. The Muslim tradition as well as much of the scholarship in the West, therefore, often ends up in a circularly reading of one in the light of the other. For an interesting approach to these issues, see Wansbrough (1978, especially Chap. 1, pp. 1–49).

Another important source for the life of Muhammad is the collections of ► *hadiths* (traditions). These are used primarily for normative purposes. The most famous collections of ► *hadiths* are that of al-Bukhari (d. 870) and Muslim (d. 875) in the Sunni tradition and al-Kulayni (d. 941) and al-Tusi (d. 1067) in the Shi'i tradition. Most of the material contained in these collections repeats that of the *sira*. However, unlike in the *sira*, where the reports are arranged in a chronological order, more or less the same reports in the ► *hadith* collections are arranged either according to the subject matter or according to the authorities who narrated them from Muhammad. This is because all genres of Muslim literary and historical tradition rely on a common pool of materials and authorities but use them for the specific purposes of their respective genres. As a result, similar problems arise when we try to use ► *hadith* collections with the aim of putting together the story of Muhammad's life.

The Traditional Account of Muhammad's Life

Despite the existing problem of sources, a somewhat standardized traditional account of

Muhammad's life is available. For an example of the traditional account of Muhammad's life see Ishaq (2001) and Watt (1961). Also, see Cook (1983). Most of it is concerned with the pre-Islamic Arabia, and Muhammad's genealogy and his military campaigns, known as *maghazi* (sing. *ghazwa*). Little information is given about his life in the period before the beginning of his prophetic mission. According to our sources, his prophetic career lasted around 22 years.

The Muslim tradition tells us that Muhammad was born around 570 CE in Mecca. An oasis town in the Hijaz area of the Arabian Peninsula, Mecca was believed to be an important center of trade at the time of Muhammad's birth. The exact date of his birth is not available, but it is usually associated with the "Year of the Elephant" or "Expedition of the Elephant," referred to as such because the march of Abraha, the ruler of south Arabia, against Mecca on an elephant took place in the same year. The date of Muhammad's death is given by the tradition as 632 CE.

Muhammad was born to Abd Allah, the son of Abd al-Muttalib and Amina, the daughter of Wahb, and belonged to the Banu Hashim section of the Quraysh tribe. The ancestry of his tribe goes back to a man named Fihr ibn Malik who lived about ten generations before the birth of Muhammad. The tribe gained prominence much later under the leadership of Qusayy, who succeeded in winning over the Meccan sanctuary by striking political alliances with various tribes. Hashim, a grandson of Qusayy, established his tribe as prominent merchants in the Hijaz setting up trade agreements with the rulers of the Roman Empire, Persia, the Yemen, and Ethiopia. He also initiated two major caravan journeys, one in the summer and the other in the winter referred to in the Qur'anic *sura* (chapter) 106.

As a sanctuary, Mecca was not only the center of trade, but also the center of pilgrimage. According to the tradition, the Meccan sanctuary had monotheistic origin and was built by Prophet Abraham. Several generations after his death, however, the Arabs abandoned the original monotheism of Abraham and the Meccan sanctuary became a pagan sanctuary. Muhammad's task was to restore the original monotheism of

Abraham. The well of Zam-Zam next to the Ka'ba is also associated with the story of Abraham's wife Hagar, their son Ishmael, and the foundation of the sanctuary in Mecca (Hawting 2005, pp. 9–10). It was the grandfather of Muhammad, Abd al-Muttalib, who rediscovered the well of Zam-Zam before the birth of Muhammad (Hawting 1999, p. 22). Apart from this, there are many other signs in the early life of Muhammad which foretold his future mission: the story about the aborted sacrifice of his father Abd Allah who was spared because he was to father an Arab prophet, the story of a woman who wanted to marry Abd Allah so that she can give birth to the future prophet, the story about a Christian monk who recognizes the future greatness of Muhammad on his journey to Syria, and many more.

Muhammad lost his parents at an early stage of his life and was cared for by his grandfather. When his grandfather died, his uncle Abu Talib took charge of his upbringing. While living with his uncle, Muhammad became involved in trade and even accompanied his uncle on trips to Syria. On one of such trips, a Christian monk named Bahira recognizes the future greatness of Muhammad and asks his uncle to protect him. Muhammad became known for his good conduct and trustworthiness among the Meccans. Eventually, a wealthy widow named Khadija employs him in her commerce, and later they get married. Unlike the custom of the time, Muhammad did not take another wife till after her death. Khadija gave birth to several of Muhammad's children. Although none of their male children survived, Muhammad is often referred to by his *kunya* (honorific title) of Abu al-Qasim (the father of Qasim). Subsequently, Muhammad married several other women among whom Aisha (d. 678) is the most famous. She was the daughter of Abu Bakr (d. 634), the famous companion of the Prophet who took over the leadership of the Muslims after Muhammad's death. Many ► *hadiths* are reported on her authority.

Muhammad was in the habit of going on retreats to Mount Hira' located not far from Mecca to contemplate in solitude. It was not until he was 40 years old that these retreats

resulted in an experience of the divine. During one such retreat, the angel Gabriel appeared to Muhammad and informed him that he had been chosen to be the messenger of God and that he should obey the command of the one God, Allah. The Muslim tradition connects the Qur'anic *sura* 96 to this incident which starts with the following verses: "Read, in the name of your Lord Who createth, createth man from a clot! Read, and Thy Lord is the Most bounteous, Who teacheth by the pen. Teacheth man that which he knew not." This event is sometimes taken to mean that Muhammad was illiterate, because in reply to Gabriel's command to read Muhammad is said to have answered that he did not know how to. It is also said that in the beginning Muhammad was puzzled about the call to prophethood, but soon began to preach what God had commanded him to.

The beginning of Muhammad's prophetic mission was very difficult. He succeeded in converting only the closest members of his family, among them his wife Khadija; his cousin Ali (d. 661), who would later become his son-in-law; and his manumitted slave Zayd. During this period, his prophetic experience remained private. Muhammad's attempts to intensify his preaching resulted in a bitter confrontation with the prominent members of the Meccan society. He was mocked for what he preached and his followers faced bad treatment. People demanded miracles from him to prove his prophetic status, but he was commanded to reply that the unseen belonged only to God (Q, 10:20). There was even an instant when Muhammad was ready to compromise with the pagan Meccans to accept their gods to secure the safety of his followers. When the followers of Muhammad began to be subjected to harsh treatment and sanctions, he first ordered them to immigrate to Ethiopia in the hope that the Christian ruler there will protect them. Meanwhile, Muhammad himself remained in Mecca and continued to look for alternative places of refuge. It is during this period that Muhammad had one of his most important spiritual experiences. One night when he was sleeping near the Ka'ba, Gabriel appeared to him and took him to Jerusalem where he was joined by

Abraham, Moses, and Jesus and led them in prayer. Then he ascended to heaven, an event that is known as *mi'raj* (ascension) in the Muslim tradition (Q, 17:1), which plays particularly significant role in the esoteric traditions within Islam.

Following the death of Khadija and his uncle Abu Talib in 619 CE, Muhammad realized that it was no longer possible to remain in Mecca. Abu Talib was in the position to protect Muhammad against the attacks of the Meccan elite thanks to his status and influence there. His death, therefore, was a heavy blow to the security of Muhammad and his followers. Eventually, Muhammad ordered his remaining followers to immigrate to Yathrib and joined them there later.

Yathrib was a small oasis to the north of Mecca, which eventually became known as *Madina* (city), short form for *madinat al-nabi* (the Prophet's city). When the first Muslims arrived in Yathrib, the inhabitants of the city, among them several ancient Jewish tribes, welcomed Muhammad and accepted him as an arbitrator in the hope that he may heal the recurrent local strife among the various groups. The event of Muhammad's move from Mecca to Medina, which the tradition places in 622 CE, is known as *hijra* (emigration). This date was later adopted as the beginning of the new Islamic calendar with the establishment of Islam as a state religion (Kennedy 1986, pp. 32–33; Cook 1983, pp. 52–53; Rippin 1999, pp. 33, 88). Those who fled Mecca to join Muhammad in Medina became known as the *muhajirun* ("emigrants"), while his local supporters became known as the *ansar* ("helpers").

In Yathrib, Muhammad succeeded in unifying the various fractions at conflict: the Jewish tribes, the Arab tribes of Aws and Khazraj, and others. The rules of this union were set in a document which came to be known as the "Constitution of Medina" (Kennedy 1986, p. 34; Cook 1983, pp. 21–22). This document was binding for Muslims and the people of Yathrib, together making up one *umma* (community of believers), who were to strive in the course of God together. All disputes were to be referred to God and Muhammad. However, the relationship with the

Jewish tribes of Medina soon deteriorated to the extent that most of them were expelled from Medina. This was often explained by the fact that the Jews were jealous that God had chosen his latest prophet from among the Arabs. In addition, the relationship between the Meccan and Medinese followers of Muhammad was also tense. They were accusing each other of hypocrisy and were suspicious of each other.

Despite these challenges, once Muhammad established his position in Medina and gathered enough support, he began his campaigns against Mecca. He aimed at disturbing the Meccan trade by attacking camel caravans and taking over the wealth of these caravans for the benefit of the Medinan community. His first major victory was achieved in 624 CE at the battle of Badr, which reinforced his position in Medina and shook the confidence of the Meccans. A string of battles between 624 and 629 CE resulted in providing Muhammad with such a strong basis, both militarily and politically, that in 629 CE he attacked Mecca itself. However, this campaign was not won by a battle but ended in the treaty of Hudaibiyya which gave the Muslims the right to perform pilgrimage to Mecca the following year. Muhammad died two years after this agreement in 632 CE by which time he had established a strong position for himself in Arabia. Following his death, these raids gave way to the conquest of the Near and Middle East by the Arabs, which went hand in hand with the spread of Islam in the region.

Historical and Religious Context

The traditional account of Muhammad's life places him squarely within a pagan setting of Arabia. His religious message is directed at idolatrous Meccans, who are surprisingly well aware of the biblical tradition. What the Muslim tradition does not tell us though is how the Meccan society relates to the Near East of the sixth and seventh century CE, an area of important political and religious developments dominated by monotheistic religions. As mentioned earlier, recent scholarship attempts to understand the period

prior to the emergence of Islam as part of the wider developments of the period in question. For an overview of the historical context prior to the rise of Islam and the early decades of Islamic history, see Kennedy (1986, Chaps. 1 and 2, pp. 1–49), Rippin (1999, pp. 4–8), and Hawting (2005, pp. 9–27). The term Late Antiquity, referred to earlier, is a new way of understanding this period in the history of the Near and Middle East. It roughly covers the third to eighth centuries CE and ends with the establishment of the Islamic state in the region. The Arabia of the seventh century CE was located between two powerful empires of the time: the Byzantine Empire in the West and the Sassanian Empire in the East. See Kennedy (1986, Chaps. 1 and 2, pp. 1–14). Several conditions lead to the success of the Arab conquest of the Near and Middle East and the eventual demise of these powerful empires: complex social and political changes, religious disaffection among some monotheistic groups, the rise of local cultures at the expense of the dominant Greek culture, and the disinterest among the general population to rise against the Arab invasion.

One particularly important change of this period was the spread of the monotheistic religions, Judaism and Christianity, and subsequently Islam in the area. The period is also marked by the rapid fall in the use of Greek and Latin languages and coming to the forefront of languages of the peripheries of the empires, such as Syriac, Armenian, Arabic, and Coptic (Hawting 2005, pp. 17–18). Therefore, looking at the rise of Islam as part of these developments helps us understand the rise of Islam in the Middle East as part of this picture with the further spread of the monotheistic traditions, continuity in sciences such as philosophy, mathematics and medicine, and some legal and social practices.

This is contrasted with the Muslim tradition's depiction of the society within which Muhammad lived as that of ignorance and idolatry. The Muslim tradition puts an emphasis on the discontinuity between the Near East of this period and the Islamic message. The term of *jahiliyya* (state of ignorance) is used in the Muslim tradition to

refer to the pre-Islamic context immediately preceding the emergence of Islam in Arabia (Hawting 1999, pp. 1–2, 4–8, 99–100, 2005, pp. 16–17). It is also used to refer to the context within which Muhammad preached his message. Although we are told of men who were in search of one true God, the society of this time is described as ignorant of God and morally corrupt and is contrasted with Muhammad's message of the oneness of God, peace, and ethical behavior. We are not told about how the society in Arabia related to the above-mentioned changes of social, political, and religious nature. The fact that we do not have this information is also related to the problem of datable sources on the life of Muhammad and the early history of Islam. Therefore, major questions concerning the understanding of the life and message of Muhammad are tied to the understanding of the historical, political, and religious contexts of his life.

Consequently, some scholars have moved the shift from the question of the authenticity of sources on the life of the Prophet to the question about the aim and role of these sources in shaping the identity of Islam as an independent religion. Scholars who take this approach are more interested in understanding why the sources for the life of Muhammad, in particular *sira* and ► *hadith* collections, exist in the form they do; why they contain certain type of material; and what function they intended to serve at the time of their emergence and during later periods rather than in questions of authenticity and reliability of these sources.

The Religion of Muhammad

The Muslim tradition emphasizes that God has revealed his final revelation to an ordinary man from among the Arabs, but the revelation itself is of the divine nature and is universal for all mankind (Q, 18:110, 41:6). Muhammad's main task as a prophet was to deliver this divine message to people. While commanding him to deliver the message, the Qur'an, 13:30 says: "Thus We send thee (O Muhammad) unto a nation, before whom other nations have passed away, that you

might recite unto them that which We have inspired in you, while they are disbelievers in the Beneficent. Say: He is my Lord; there is no God save Him. In Him do I put my trust and unto Him is my recourse."

The revelation was sent down through an angel in segments over more than twenty-year period (Hawting 2005, p. 10). It was not revealed in the order in which the Qur'an in its present form exists. The present order of the text came about after the death of Muhammad. The Qur'an, 33:40 emphasizes the position of Muhammad as a prophet: "Muhammad is not the father of any man among you, but he is the messenger of Allah and the Seal of the Prophets; and Allah is ever aware of all things." Thus, Muhammad is not the only prophet, and there have been many prophets before him, but he is the seal of the prophets. Muhammad is asked to warn by the book of the day of judgment, remind his people of the nations and prophets' past, and give good tidings. His audience is asked not to worship anything but God and not to associate anything with him (Q, 6:162–163). Moreover, Muhammad's task was to serve as the final link in the chain of many other prophets (Adam, Noah, Abraham, Moses, and Jesus) and complete what had been revealed to them. But Muhammad has a distinguished position too; he is to deliver the final message, but at the same time reaffirm and continue the original monotheism of Abraham (Q, 3:67–68) (Rippin 1999, pp. 16–19; Rubin 2005, pp. 444–445). The authenticity of his message is ascertained by many verses of the Qur'an (Q, 2:119, 252, 4:170, 9:33, 35:24).

Although Muhammad's name is mentioned only four times in the Qur'an, there are various words which have been taken to indicate his relation to God. He is called *rasul Allah*, the messenger that conveys the divine message. He is *abd Allah*, the servant that serves his God and obeys His command. He is the *bashir*, the announcer of good tidings to his fellowmen and the *nadhir*, who warns them and prepares them. He is the *shahid*, the witness of the glory and greatness of God. He is also the *da'i* who summons his people to goodness and to the *sirat al-mustaqim* (the right path). And he is the *siraj*

munir (the light-giving lamp) that illuminates the right path for those who choose to follow him (Rubin 2005, p. 440).

The Qur'anic word for God is Allah. The central message of Muhammad's teaching is the unity and oneness of God. The God of the Qur'an is omnipotent, has no similitude, and is the creator of all that is in the heavens and on earth. He is also transcendent, all-powerful, magnificent, yet compassionate, merciful, forgiving and just. God in Islam has attributes, which are expressed by his 99 beautiful names. He has revealed his will and message to human beings through His prophets, which has been completed by His revelation to Muhammad.

The Islamic law, *shari'a*, is a divine law; the basic principles of which are reflected in the *sunna*, the normative example of Muhammad known from the ► *hadiths*. It is interpreted and transmitted by Muslim scholars of jurisprudence. The two major sources of law common to all Muslim groups are the Qur'an and the *sunna* of the Prophet (Rippin 1999, pp. 74–80).

The official five pillars of Islam (sometimes referred to as rituals) are the *shahada* (the confirmation or testament of faith "There is no god but God, Muhammad is the messenger of God"), *salat* (the five-times prescribed daily prayer), *sawm* (fasting of the month of Ramadan), *zakat* (alms tax), and *hajj* (pilgrimage to Mecca during the month of Dhu'l-Hijja). These are vaguely described in the Qur'an, but one can find detailed description in other Muslim sources, notably the ► *hadiths* (Rippin 1999, pp. 86–99).

The Qur'an as well as the *sunna* emphasize ethical principles of charity, compassion, fulfillment of one's commitments, trustworthiness, and courage. These are the principles that the life of Muhammad epitomizes for every Muslim. Many verses of the Qur'an associate the belief in God with charitable and good deeds, emphasizing that being ethical is part of fulfilling God's command. An example of this is the Qur'an, 47:2: "And those who believe and do good works and believe in that which is revealed unto Muhammad – and it is the truth from their Lord – He riddeth them from their ill-deeds and improveth their state." In Islam, such ideas about good and ethics matured over time and successfully incorporated the

teaching of Muhammad with elements from the pre-Islamic Arabian, Greek, and Persian traditions under the unifying Islamic framework. It was further developed in the Muslim literary tradition which built on what the ► *hadiths* and Qur'anic verses had to say on the subject.

The Centrality of the Figure of Muhammad in Islam

The major characteristic which sets Islam apart from other monotheistic traditions is the doctrine of the unity (or oneness of God) and the prophethood of Muhammad. The *shahada* is a witness to these two essential principles and thus shows the centrality of the belief in Islam that Muhammad is the messenger of God. But the centrality of Muhammad's position in Islam goes beyond that. Muhammad's example plays central role in establishing Islam as an independent religious tradition. The accounts of his life function in a way that their normative role in elucidating the various aspects of Islam is as important, if not more so, as their task of relating the story of Muhammad's life. The establishment of most important aspects of Islam is projected back to the life example of Muhammad with the intention of confirming him as their founder. That is why the *sira* of Muhammad, the scripture of Islam, and his *sunna* are most important in this respect.

Muhammad's main task as a messenger was to deliver God's revelation to mankind, yet the Qur'an depends on his *sira* to provide a framework for its understanding. *Sira* was one of the first types of literature to develop in the Muslim tradition which continued to influence other genres of Muslim literary and historical tradition as they grew out of it and their development went hand in hand with its development. The *sunna* of the Prophet is the major source of Islamic law in terms of its importance and size. The idea of a *masjid* (mosque) as a place of prayer and worship is also traced back to the example of the early Muslim community lead by Muhammad in a congregational prayer. Although its form developed and transformed over time, the basic function and form of a mosque remained the same.

In sum, Islam as an independent monotheistic religion has its own prophet, scripture, religious law, calendar, place of worship, and rituals. Their origins, function and form are traced back to the life time of Muhammad and are authorized by his example. Muhammad's life is accepted as a model for every Muslim because while reaching the highest spiritual experience (such as his ascension to heaven on the night of *mi'raj*), he is said to have remained true to his worldly commitments of taking care of his family, managing the affairs of his community, and leading his followers. His example, therefore, continues to inspire Muslims in the way they practice their religion and live their lives today.

Multi-criteria Decision Analysis (MCDA)

M. Teresa Ortuño

Department of Statistics and Operational Research I, Universidad Complutense de Madrid, Madrid, Spain

Multiple-criteria decision analysis, or multiple-criteria decision-making (MDDM) is a subdiscipline of operations research that explicitly considers multiple criteria in decision-making environments. MCDA can be defined as the study of methods and procedures by which concerns about multiple conflicting criteria can be formally incorporated into the management planning process. There have been important advances in this field since the start of the modern multiple criteria decision-making discipline in the early 1960s. Different schools of thought have developed for solving MCDM problems, being the most known the multiobjective mathematical programming school, the goal programming school, the French school with its outranking methods, the evolutionary multiobjective optimization school, the analytic hierarchy process, the fuzzy-set theory, or the multiattribute utility theory.

Related Terms

[Medieval Arabic music](#); [Music literature](#)

Little is known of medieval Arabic musical repertoire save for an exercise for the ‘ūd by al-Kindī (d. after 870) where the notation is expressed in terms of fingers and frets, and for transcriptions by Ṣafiyy al-Dīn al-Urmawī (d. 1294), of songs and pieces where durations and pitches are given. Musical notation in the early ‘Abbāsīd era was apparently very precise yet rarely used. We know from *Kitāb al-Aghānī* (*Book of Songs*) that Prince Ibrāhīm ibn

al-Mahdī (d. 839) asked Ishāq al-Mawṣilī (d. 850) to send him a notation of a song the latter had just composed; Ishāq did and the notation enabled Ibrāhīm to perform it (10: 105). We do not know the nature of the notation used, but that it was used in the rare circumstance when the performer was far away from the composer and thus unable to learn it orally. In addition to the type of notation mentioned above, al-Fārābī (d. 950) invented a very precise syllabic notation for rhythm influenced by the fifth-century Byzantine treatise *Anonymous Bellermand* and complemented it with geometrical symbols.

What medieval Arabic music lacked in notation, it made up with reliable sources in the field of music theory and literature. Music theory relied on the writings of the practitioners, especially Ishāq al-Mawṣilī; the *lingua franca* used was that of the skilful musicians, a language rich in metaphors to explain musical practices. Theory also relied on models derived from Arabic and Persian humanities. For instance, it borrowed from grammar and phonology the sounds of case endings (nominative, accusative, and genitive) to denote loud, moderate, and soft musical sounds. From prosody it borrowed the concepts of lengthening and shortening syllables to describe elongating and reducing musical bars. From poetics it borrowed the poetical device known as *taṣdīr* (where the word in the rhyme is quoted at the beginning of the verse) to describe the upbeat/anacrusis in music. From rhetoric it borrowed the concept of metaphor to explain the attacks at the end of a bar that facilitate the passing and transference of attacks to the next bar. From Qur’anic sciences it borrowed the term *tartīl* and *ḥadr* (slow and fast recitation of the Qur’ān) to describe slow and fast tempo. Theory also relied heavily on the works of the Greeks: thanks to the translation movement started in the Umayyad era and culminating in the *Bayt al-Ḥikma* (House of Wisdom) in the ‘Abbāsīd era in Baghdad, the methodology of Ancient Greek theory, philosophy, and mathematics were made available in Arabic translations via Syriac. The first to fuse Greek and

Arabic theory was the philosopher al-Kindī; not being a practical musician, his work did not always reflect musical practices. Al-Fārābī being both a performer and logician was more successful. His work owes much to the Arabic practitioners but also to Euclid, Aristotle, and Aristoxenus. From Euclid's *Postulatum* he borrowed the concept of lengthlessness of the point and applied in music to the timelessness of the attack; from Aristotle he borrowed the standard of time measurement, and from Aristoxenus, the definition of rhythm as organized durations and the idea of rhythmic variations. The latter, having a practical and aesthetic musical function, preoccupied al-Fārābī so much that he produced an unsurpassed theory of ornamentations.

Music literature, influenced by Persian and Arabic models, was included in many disciplines: *adab* (belles-lettres) and poetical literature; anthologies and anecdotal literature; *ṣamāʿ* literature (lawfulness or unlawfulness of listening to music); biobibliographical literature; historical and geographical literature; and dictionaries. The most important document in music literature is *The Book of Songs* of al-Iṣbahānī (d. 967), compiled over a period of fifty years. The monumental collection, now in 10,000 pages, treats in anecdotal form the activities of poets and musicians inside and outside the court from early Islam to the beginning of the tenth century. His sources include oral and written history related by the poets, the musicians, their descendants, and friends. The anthology encompasses much now-lost material and sheds light on anthropological aspects of musical practices: socioeconomic status of male and female singers; uses and functions of songs; role of musicians as refined friends of the aristocracy; evaluative criteria for musical excellence; and process of composition and improvisation. Songs punctuated many aspects of social life, including birth, circumcision, wedding, love, farewell, greetings, and sickness; they described nature and wine; they also celebrated military victories and praised the rulers on their accession to the caliphate and vizirate. Thus music making was very widespread; it was

unlawful only when the performance context was, e.g., when interfering with prayer time, involving alcohol consumption or in the company of badly behaved individuals.

Mutakallimun

Victoria Ziva Frappollo
Department of Religious Studies, McMaster
University, Hamilton, ON, Canada

Practitioners of kalam (Islamic speculative theology). Kalam seeks to prove the Muslim faith through the dialectical use of reason. The medieval kalam argument in favor of the demonstrability of the created nature of the world (a form of the cosmological argument) was opposed by Moses Maimonides on the grounds that reason does not suffice to prove either the created or eternal nature of the universe, and that our belief in creation must have its source in revelation.

Mystical and Religious Experience

Catharina Stenqvist
Centre for Theology and Religious Studies,
Lund University, Lund, Sweden

This kind of experience can be classified in various ways. When any experience includes sense-perceptual or introspective content, it is classified as an *extrovertive* experience. When not extrovertive, the experience is *introvertive*. An experience of “nothingness” or “emptiness,” in some mystical traditions, and an experience of God resulting from a disengagement from sense experience, would be an example of introvertive experiences.

One might also make a distinction between *theistic* and *nontheistic* experiences. Theistic experiences are purportedly of God while nontheistic experiences can be of an ultimate reality other than God or of no reality at all. There is also a rich family of experiences of *union* with God. “Union” involves a falling away of the separation between a person and God, short of identity.

Description

The term “mysticism” comes from the Greek “myo,” meaning “to conceal.” In the Hellenistic world, “mystical” referred to secret religious rituals. In early Christianity, the term came to refer to allegorical interpretations of Scriptures and to hidden presences, such as that of Jesus at the Eucharist. Only later did the term begin to denote mystical theology, which included direct experience of the divine. Mysticism usually centers around a practice or practices intended to nurture that experience or awareness. Mysticism is a phenomenon within religion and religious traditions, but it also occurs independently to defined religion. Mysticism as an element in religion some argues is an essential part of religion. The point debated is whether mysticism is reducible to religion or not.

The term “mysticism” is used to refer to beliefs and practices which go beyond the liturgical and devotional forms of worship of mainstream faith, often by seeking out

inner or esoteric meanings of conventional religious doctrine.

Mystic traditions generally form subcurrents within larger religious traditions – such as Kabbalah within Judaism, Sufism within Islam, Vedanta within Hinduism, and Christian mysticism within Christianity – but are often treated skeptically and held separate due to their emphasis on personal experience over doctrine.

Mysticism might be studied within a wide variety of disciplines, such as church history, dogmatics, exegetics, psychology, and philosophy of religion. Research on “mysticism” has been conducted within these diverse disciplines, through a vast diversity of methodological applications, and with a variety of phenomena in mind (McGinn 1999). Psychologists and sociologists of religion have primarily focused on the psychological mechanisms and qualitative aspects of mystical experience, as well as on the pathological and therapeutic outcomes of experiences classified as “mystical.” These investigations largely circle around the experiences of mystics and the states of consciousness confirmed by their reports, by the results of various neurological and biological measures, and by any postexperiential attitudinal and/or behavioral changes that may have been reported or observed. Exegetical approaches, on the other hand, focus less on the experiences of mystics and more on their writings – and perhaps other expressive modes such as art or music – which, of course, are not always about their mystical experiences per se. Hermeneutical methods as well as theories of language and of mystical truth claims dominate the exegetical disciplines.

Mysticism is related to epistemology to the extent that both are concerned with the nature, acquisition, and limitations of knowledge. However, where epistemology struggles with foundational issues, mystics often appear more concerned with process as the means to true knowing (Cupitt 1998). One question is therefore, what kind of knowledge is involved and how is it possible to claim objective truth?

A vital area for the study of mysticism is religious experience or mystical experience; the two words are more often than not used interchangeably. A distinction is made between apophatic and

kataphatic mysticism concerning what can be said of objects and state of affairs that mystics experience. Examples of other keywords are consciousness, religious language, and the question whether language is descriptive or not and what is expressed by metaphors, analogies, and symbols.

Mysticism as we know it today originated with William James and his standard work *The Varieties of Religious Experience* 1902. James claimed four criteria for the possibility to discern religious or mystical experience: ineffability, noetic quality, transience, and passivity. James' criteria have influenced the understanding of mysticism, and most researchers in one way or other discuss them either embracing them or rejecting them. At the beginning of the last century, Evelyn Underhill made mysticism attainable for the broad public by her book *Mysticism*. It is more a historic outline than a profound work of theology or philosophy.

New within the studies of mysticism is the gendered aspect and questions pertaining to feminism. Grace Jantzen maintains that a connection can be traced between the domestication of women and the domestication of religion such that claims to religious experience become permissible for women in direct proportion to the decline of overt public importance of religion.

A lively discussion has been focusing the character of religious or mystical experience (Kimmel 2008). Steven T. Katz argues that mystical experience is contextual, that is, always shaped by pre-experiential expectations, beliefs, and concepts resulting in mysticism being conservative in character. Robert Forman, challenging Katz' understanding, argues that there are indeed such things as "pure consciousness events" – events that are independent of any given religious tradition. By and large, when all is said and done concerning the theoretical scholarly aspects of mysticism, mysticism is a way of life pertaining to a certain outlook on the human existence.

Mysticism in Islam

Richard J. McGregor
Religious Studies Department, Vanderbilt
University, Nashville, TN, USA

Related Terms

[Dervish](#); [Sufism](#)

Description

The most widely used term for the Islamic mystical tradition is "► [Sufism](#)," with its practitioners known as Sufis. The word "dervish" is also common. From the mid-eighth century, roughly one century after the rise of Islam, distinctly Sufi teachings were formulated in both the majority Sunni branch and among the Shi'a. The earliest regions of activity were Iraq and Khurasan, but Sufism quickly established itself throughout the Muslim world. From the twelfth century onward, various Sufi orders developed, each based on the teachings of a saintly founder. Sufism has

balanced the literalist and exoteric impulses of the religion and, in the modern period, become a foil to Islamist and Wahhabi interpretations.

Self-identification

Science

In the premodern period, as articulated in poetry, philosophy, and ethics, Sufism was often considered one of the “sciences” (Ar. *‘ulûm*) of religion. Some grounding in this branch of knowledge was expected of scholars and other Muslim elites. Knowledge of the self and one’s direct experience of the divine are the primary concerns of Sufism. Spiritual anthropology, cosmology, visionary experiences, and ascetic practices are all important categories of such mystical speculation.

Religion

Sufism sees itself as essential to Islam, particularly as a complementary dimension to that of religious law or Sharia. However, the most extreme mystical practices and esoteric theorizing have normally been criticized and rejected by mainstream religious scholars. In the modern period, Wahhabism and Islamist groups such as al-Qaida have sought to reject Sufism categorically – often lumping it in with Shi’ism and other “heretical” movements. Wahhabism is a modern revivalist movement in Arabia, characterized by literalism, intolerance toward Shiism, Sufism, and all religious practices not established at the time of the Prophet and the earliest Muslim community.

Characteristics

Sufism has much in common with the mysticism of other monotheistic traditions. Perhaps the most obvious similarities are their Neoplatonic and gnostic tendencies.

Relevance to Science and Religion

The systematic understanding of self – its nature, appetites, and training – constitutes a premodern

psychology. Some contemporary Muslim mystics have claimed that Sufism presaged modern Western psychoanalysis.

Sources of Authority

The sources of authority are the Islamic revelation, as preserved in the Qur’an and the model of the prophet Muhammad, as well as the teachings of prominent Sufis whose esoteric knowledge is based on visionary and ecstatic experience.

Ethical Principles

A significant component of Sufi discourse revolves around the concept of *adab*, or proper comportment. While the essential Islamic conception of right action rests largely within the purview of Sharia, *adab* treats ideas relating to personal introspection, such as sincerity and intention. Reflections on proper comportment also dealt significantly with the relationship of Sufi adherents to their teachers and the duties of aspirants toward one another.

Key Values

Sufism promotes direct personal knowledge of God, which when coupled with observance of divine law leads to the perfection of the human condition.

Conceptualization

Sufism expands variously on the esoteric and symbolic dimension of all of these concepts.

Relevant Themes

Since great emphasis has been placed on improving the self in order to facilitate rapprochement with the divine, Sufism has developed complex models of the psyche. Controlling the “lesser”

impulses, and improving one's noble faculties, leads the individual to mental and spiritual completion and thus true happiness.

Myth

Angela Ales Bello
Lateran University, Vatican City, Italy

Related Terms

[Fable](#); [Fairytale](#); [Fictional tale](#); [Folktale](#); [Legendary](#); [Story](#); [Tale](#)

Description

Myth is a Greek term *μῦθος* that means “word” or “story.” In all cultures, myths are recounted by ritual mimes and celebrated in public festivals

with the aim of appeasing the gods or warding off evil. They are the originating source of the religious institutions of a clan or a city. Myth is always the product of a collectivity.

In Western cultures, from the birth of Greek *Logos*, interpretations of myths are multiple. *Logos* is understood to be the foundation for philosophy and the sciences. It attempts to comprehend myths in their individual form and even tries to eliminate them as they are judged to be fruits of the imagination and, therefore, false. Interpretations are mostly linked to philosophy and, more recently, to historical-philological investigations, cultural anthropology, sociology, history of religions, psychoanalysis, and the phenomenology of religion.

From the modern philosophical perspective, myth is born from the anxiety that stems from standing before God (G.B. Vico), from the infancy of humanity (C.G. Heyne), from anguish (Herder), or from the symbolic expression of the ideal (G.F. Schelling). Cultural anthropology and sociology are closely related, and, according to E. Durkheim and J. Harrison, social facts and institutions are dramatized in rituals narrated by myths. For J. G. Frazer, myth allows us to understand early thought, which was later taken over by science. B. Malinowski considers myths as expressing social organization. Following the line of cultural anthropology, L. Levy-Bruhl sees myths as expressions of human inferiority that employ prelogical modalities proper to infantile or schizophrenic language, whereas C. Lévi-Strauss views myths as a communicative system to which a structural analysis may be applied. In the case of the latter, myths are words with respect to a system of fixed underlying structures constituted by codes.

From the historical perspective of comparative religion, G. Dumezil maintains that the religious system of a group of humans expresses itself on three different levels: the unconscious conceptual structure, myths that configure this structure, and rites that concretize it. There is a circularity that marks the relation between myth and rite.

Concerning psychoanalysis and depth psychology, S. Freud defines myths as deformed

dreams in which the desires of whole nations are realized, ancient dreams of a young humanity, whereas C. Jung develops a theory of archetypes. Here, myths, fables, and dreams use the same symbols and images because they are archetypes of the human psyche; they are constitutive of our genetic patrimony. An attempt to separate myth from religion was carried out by the “discovery” of language with the comparative grammar of Michel Foucault, the comparative mythologies of K.O. Mueller, and the anthropological school of A. Lang. For Mueller, who studies the epistemological status of myth through the genesis of language that develops in three phases, the birth of myth arises in the second phase. Here, anthropomorphic representations are substituted for the direct relation between sound and object, giving birth to linguistic metaphors; words possess more or less wide semantic fields, and this allows myths to appear. For Lang, myth is a larger product of the human mind that is based on a wild metaphysics.

In general, the interpretation of myth as a prelogical form, dream state, or as wild is distinguished from an interpretation of myth as *Logos*, which views the former as the product of an infantile mentality that is not able to understand myth’s independent essential value. This has many consequences for culture, especially in the West. Western culture, proclaiming itself to have surpassed myth through *Logos*, declares itself superior in terms of its cultural expressions that are still connected with myth.

It is for this reason that a reading of myth that makes evident its characteristics and allows it to live in its specificity is more convincing. In particular, I refer to the reading given by the phenomenology of religion, whose main proponent is G. van der Leeuw, according to whom myth is the repeated declaration of a powerful event. Here, a declaration means repetition, and, therefore, being connected to ritual, it is a celebration in words.

The mythical word, then, is different from the concept because it does not abstract from life; rather, it gives form to life, calling and allowing it to surge forward. In this sense, it is not an explanation of reality; it has a poetic value, that

is, it constructs life while giving it a truth value. This is understood, above all, in relation to time. Time’s temporal flow is arrested in myth. Repetition occurs outside of time and is guaranteed by the suspension of time itself. Moreover, the impossibility of separating myth from the sacred is witnessed by the permanence of such an attitude as conveyed in more complex religious expressions, for example, the liturgy of the Roman Catholic mass, which reintroduces at every occasion the powerful event of the saving death of Christ, even in a context that is globally understood as not mythical.

Following the approach of the phenomenology of religion, one can mine further the genesis of myth. It can be interpreted as the particular expression of the presence of the sacred and religious, whose content is connected to that dimension that Husserl calls phenomenological “hyletics.” This refers to the centrality of bodily movements and psychic relations, which are understood as instruments through which the sacred configures itself. These very instruments express themselves through words, tales, and rituals, ultimately separating themselves from the sacred (A. Ales Bello). Undoubtedly, myths disclose by hiding the face of the sacred or divine power. They are the manifestation of hierophanies, as M. Eliade has demonstrated.

That myth does not exhaust itself in the archaic age of Western culture and that it continues to live in the religious dimension is witnessed by, for example, the ancient Egyptian myth of Isis, which continues to live on in the Christian era. This myth probably refers to the archaic divinity, who is known as the God Mother or Great Mother. We find traces of her through archaeological finds in all parts of the world. She later appears under the guise of many other female divinities. Think of the multiplicity of divinities constitutive of the Hindu pantheon that represent the diverse functions of the goddess, both good and bad. At the same time, in recorded history, the goddess takes on the name of Isis and, from time to time, is linked to other female divinities, even to other concepts of the female divine. We find traces of this in lands that border the Mediterranean and even in distant

places like Britain. But what we find in the historical period bears witness to the fact that there is a separation between the cult of those faithful to the myth and the theoretical interpretation of this myth.

This is very clear in Plutarch and Apuleius as they treat the myth of Isis with great care, but they seek to rationalize it. In fact, Plutarch maintains that the myth is the reflection of a superior truth, and he considers Isis as the expression of a unique rationality with a unique provenance that utilizes philosophical categories proposed by Plato, ultimately allowing the name of the goddess to become identical with knowledge itself, *isia*. Apuleius understands the religious message more directly as he speaks about an initiation into the cult of the goddess. In every case, the initiation has knowledge of the ultimate religious truth as its end, and all of this occurs with the understanding of he or she who lives in the dimension of *Logos*.

Events linked to the myth of Isis can be considered emblematic of the change of the Western mentality from *mythos* to *Logos*.

We can delineate two levels of myth. First, there is the sacral religious in which myth continues to have a specific sense, even despite notable changes throughout the ages that are designated by an archaic mentality – changes of which we can only catch a glimpse. Second, there is the philosophical level. Here, myth is subjected to that investigation that we continue to enact in different forms. As we have seen, the birth of a multiplicity of disciplines, which in the West have progressively detached themselves from the great trunk that we call philosophy, has created a situation where interpretations are presented in various ways, ultimately destroying the very sense of myth at the moment in which it empties itself of the meaning of the sacred that characterizes it. The vision of the world generated by myth, in fact, was a vision in which diverse forms of knowledge were not rendered distinct; rather, only knowledge had a profoundly religious connotation.

The process of desacralization, which typifies certain sectors of twentieth-century culture, justifies the contemporary use of the term myth to

indicate an ideology or a utopia as an ingredient of a collective lived experience of a social and political character that arouses the collective imagination, creating, for example, through cinema the phenomenon of the diva. There is a reversal, then, of the very same temporal perspective. This is why myth today has a projective value for the future: undoubtedly, it maintains, even from far away, links to a desacralized “power.” Here, we are dealing with visions of the world different from those in which myth was originally constituted, and it is only by considering it as a “vision of the world” that it is possible to maintain the same term for diverse contents.

Myths

Gregory Allen Robbins

Department of Religious Studies, University of
Denver, Denver, CO, USA

In everyday parlance, in popular culture, “myths” denote fictional stories, fanciful or silly stories, stories that are *not* true. “Myth” is used

pejoratively. In religious and biblical studies, narratives that are identified as myths or as “mythic” are those that religious communities value as *most* true. Alan W Watts, historian and philosopher of religion, offered this useful definition: “Myths are a complex of stories – some fact, some fiction – that, for various reasons, humans regard as demonstrations of the inner meaning of the universe and of their own existence” (*Myth and Religion*, 1996, *opus posthumous*).

Nag Hammadi Library

Carl Raschke

Department of Religious Studies, University of
Denver, Denver, CO, USA

Not so much an actual “library” but a collection of intact, ancient Gnostic texts – translated early on from Greek into Coptic – that were discovered in Egypt in 1947. Their discovery and subsequent translation revolutionized the scholarly understanding of Gnosticism during the Hellenistic period.

Names of God

Dan Cohn-Sherbok

University of Wales, Cardiff, UK

In the Jewish tradition, names of God are either conceptual or proper. In ancient literature, the latter is more frequent, but the original significance of such names is often not easy to determine. The choice of one name over another generally depends on its significance. R. J. Z. Werblowsky and G. Wigoder note that according to most biblical scholars, the two most important biblical names of God are YHVH (Tetragrammaton) and Elohim. Of the two names, YHVH

(consisting of the letters yod heh, vav, heh) is the most frequent. According to rabbinic sages, this is the essential name of God. It appears that this name is connected with the phrase “ehyeh asher ehyeh” (“I shall be what I shall be”) (Ex. 3:14) (Werblowsky and Wigoder 1997). According to a number of Jewish philosophers including Moses Maimonides, this expression denotes eternal existence. This holiest of names was never pronounced except once a year by the high priest in the Holy of Holies on Yom Kippur. According to rabbinic tradition, once or twice in 7 years the sages entrusted to their disciples the pronunciation of the Tetragrammaton. The original pronunciation of YHVH is now unknown: when pronounced it is substituted by the name Adonai (my Lord), a term which was used from the second century BCE. The combination in the Hebrew Bible of the consonants – yod, hey, vav, hey – and the vocalization for Adonai resulted in the pronunciation of YHVH as Jehovah. Other names of God in the Bible are Adonai (Lord), El (Strong), Shaddai (Almighty), Elyon (Most High), Yah (a shorter form of YHVH), and Ehyeh (I shall be). The name Elohim is also used to refer to heathen Gods (Ex. 20:3) and human judges (Ex. 22.7).

There are over 90 names for God in rabbinic literature. The most frequent are Ha-Makom (The Place), Shamayim (Heaven), Ha-Kadosh Baruch Hu (The Holy One, blessed be He), Ribbono Shel Olam (Master of the Universe), Shekhinah (Divine Presence), Avinu (Our Father), Malkenu (Our King), and Gevurah (Power). Medieval

Jewish philosophers used a range of other names for God including First Cause, Prime Being, Cause of Causes, Beginning of Beginnings, Creator, and Ha-Shem Yitbarakh (The Name, blessed be He) (Jacobs 1968). In kabbalistic sources, the term En Sof (Infinite) is used to refer to God as he is in himself. The Sefirot (divine emanations) are names for various aspects of the Divine: (1) Keter (Crown), (2) Hokhmah (Wisdom), (3) Binah (Understanding), (4) Hesed (Lovingkindness), (5) Gevurah (Power), (6) Tiferet (Beauty), (7) Netzah (Victory), (8) Hod (Splendor), (9) Yesod (Foundation), and (10) Malkhut (Kingship). The Holy One, blessed be He denotes the male principle in the Deity; the Shekhinah refers to the female principle. There are also three more esoteric names of God in kabbalistic sources: the 22-letter name, the 42-letter name, and the 72-letter name (Jacobs 1968). In modern times, some Orthodox Jews refer to the divine by the name Ha-Shem (literally, “the Name”). It is also not uncommon for Orthodox Jews to spell the word God as G-d; this practice is based on rabbinic teaching about the need for reverence for God. In non-Orthodox movements, this practice is rarely followed.

[Narrative](#)

Description

Narrative psychology is the comprehensive designation for narrative approaches in a variety of research areas in psychology, such as personality psychology, developmental psychology, social psychology, health psychology, and organizational psychology. The basic idea is that

human beings make sense of their world and their selves above all through ► [narrative](#), developing and organizing knowledge, memories, intentions, life histories, and personal identities in narrative patterns. As a subdiscipline, narrative psychology started in the 1980s to recapture the originating impulse of the so-called cognitive revolution in the 1950s, which addresses how people construct meaning (Bruner 1986), but where the cognitive revolution originally tried restoring mind to human science, narrative psychologists stress “narrative” as the adequate concept for analyzing human organization of action and experience over time and in space. In this context, narrative is understood as a meaningful temporal configuration of states and events. The organizing theme of this kind of meaningful structure is usually called the ► [plot](#). The concept of narrative is thus not limited to the result of narration or an act of verbalization in storytelling but is perceived as an inherent structure of human action and experience. The narratory principle that human beings perceive, think, remember, feel, imagine, act, and make moral choices according to narrative structures lends itself to a variety of research perspectives, in which “narrative” functions as a root metaphor for the construction and adoption of analytical perspectives and scientific models and methods (Sarbin 1986).

One focus of research in narrative psychology is on narrative as a cognitive structure that culminates in recent research on narrative intelligence and cognitive narratology (Herman 2003). This approach relates to cognitive psychology research on mental structures, such as story schemata, story grammars, narrative superstructures, or event-situation structures. In addition, Jerome Bruner’s distinction between the paradigmatic and the narrative modes of thought, both based on different operating principles, has been especially influential (Bruner 1986). Whereas the former aims at abstraction and generalization by transcending particularities and formulating a well-structured argument, the latter re-situates the abstract and the general in temporal and local contexts to embrace the concrete and the specific by formulating a good ► [story](#). This research on narrative as a basic cognitive endowment has

demonstrated in a number of research projects that narrative is a highly adaptable mode of cognitive and communicative practice, supporting a variety of problem-solving activities – even within different types of scientific research.

The perspective on memory processes as active reconstructions of the past and the identification of special kinds of memories organized as narratives, such as episodic memories and autobiographical memories, facilitated another well-known research focus, namely, the narrative approach in personality psychology, which derives from the story-based psychoanalytic and humanistic traditions in personality psychology and clinical psychology. One important development in this context is Dan P. McAdams’s life story model of identity, which asserts that people living in modern societies function as their own biographers and provide their lives with unity and purpose by constructing from adolescence onward internalized and evolving narratives of the self, complete stories with particular narrative tones and forms (such as comedy, romance, tragedy, satire), images, ideological settings, (nuclear) scenes, more or less archetypal characters, themes, and familiar plot lines (such as the redemptive self) (McAdams 2001; Narrative 2006). All storied approaches understand the construction of identity as a psychosocial project, and recent developments focus on a more pragmatic concept of story, implying a storyteller and an audience and thus explicitly addressing issues of context. They try to understand the construction of identity as a long-term autobiographical project and as a socially situated enterprise. Researchers who have emphasized the importance of the performance of “small stories” and of everyday conversational storytelling in ordinary social interactions for constructing identities have shifted their focus to narrative in the context of its telling and to the fact that stories are also collective or collaborative productions and social interactions within a particular sociocultural context (Narrative 2006). Meanwhile, narrative psychologists are becoming increasingly interested in the complex relation between narrative form and content, narrative performance, referential content, and sociocultural contexts of

storytelling. Recent research questions also concern the relationship between cultural narratives, group narratives, and personal “small” and “big” narratives, especially in the context of intergroup and international conflicts (Hammack 2008). Generally, narrative studies have inspired a new integrative framework in personality psychology, as well as transdisciplinarity in research on identity (Narrative 2006; Hammack 2008).

In addition, narrative practices have been adopted in various professional fields, such as in therapy, counselling, and mediation. In psychotherapy, for example, we find two different applications of the narrative: on the one hand, there are attempts to incorporate the concept in psychological models of the therapy change process, and on the other hand, there is the concept of a post-psychological narrative therapy, in which the concept of changes in psychological processes is replaced by the notion of changes in performed narratives linked to changes in social relationships (Narrative 2006).

Self-Identification

Science

Narrative psychology self-identifies as a human science and maintains that psychological description, understanding, and explanation of the human realm of meaning require concepts and methods from the social sciences and the humanities. Some (narrative) psychologists criticize the rigid distinction between the sciences and the humanities as dysfunctional for research in psychology, arguing that narrative studies have the potential to reconcile quantitative and qualitative methodologies.

Characteristics

Narrative psychology is distinctive among the other subdisciplines in psychology by virtue of its special focus on the concept and study of narrative and its special affinity with narratology and dramaturgical and literary discourses. It does not pertain to the traditional subdisciplines

of psychology denoting a particular field of research, such as social psychology, personality psychology, and developmental psychology, although it does pertain to the subdisciplines identified by a particular (meta) theoretical perspective, such as behaviorism, cognitive psychology, biological psychology, cultural psychology, and social constructionism. These distinctions rely on fairly heterogeneous criteria for classifying subdisciplines in psychology, and we could also argue that narrative psychology overlaps partially with some of the other subdisciplines.

Relevance to Science and Religion

Narrative psychology in general has no special affinities with this area. But narrative approaches in the subfield of psychology of religion address the narrative structure of the varieties of religious experiences, religious experiences and practices as enacted narratives, religious narratives as performances (e.g., conversion narratives), narratives as resources for and representations of individual or even collective religious experiences and practices, and religion as part of individual and collective identity constructions. They do not address ontological or epistemological issues with regard to scientific or religious world views. Narrative psychology can also contribute to this field by analyzing the variety of collective and individual narratives explicitly or implicitly included in debates relevant to this area.

Sources of Authority

The sources of authority for this subdiscipline can be traced back to Aristotle's *Poetics*, which included an outline of classical concepts, such as conceptualization of the dramatic forms of tragedy and comedy as a mimesis of human action; construction of a plot as the sense of the story, as the synthesis of its different parts; and the purge of emotions (catharsis) as the psychological effect of these narrative forms (Aristotle 1968). But psychologists' explicit recognition of stories as relevant to their discipline since about

the 1980s relates to a development that emerged only in the mid-1960s, in which narrative has become a central concern in a wide range of disciplinary fields and research contexts. This cross-disciplinary narrative turn is exemplified by Mitchell's edited volume *On Narrative* (1981), featuring seminal contributions from scholars such as Hayden White, Roy Schafer, Frank Kermode, Victor Turner, and Paul Ricoeur (Mitchell 1981). The work of Charles Taylor, Alasdair MacIntyre, and Arthur Danto about narrative sources of the self, a virtue ethics linked to the narrability of human life and narrative explanations in historiography, has had a major impact on narrative psychology as well (Sarbin 1986; Polkinghorne 1988). This influence is demonstrated in authoritative publications from the 1980s, such as the volume *Narrative Psychology: The Storied Nature of Human Conduct* edited by Theodore R. Sarbin (Sarbin 1986) and including contributions, for example, by Kenneth and Mary Gergen, James Mancuso, Karl Scheibe, Donald Spence, Elliot Mishler and the editor; several publications by Jerome Bruner, for example, *Actual Minds, Possible Worlds* (1986); and Donald Polkinghorne's (Polkinghorne 1988) *Narrative Knowing and the Human Sciences* (Sarbin 1986; Bruner 1986; Polkinghorne 1988). All these authors have argued convincingly that human beings live with stories or exist narratively and that narratives are in one way or another constitutive of human reality. They paved the way for basic research on narrative as a mode of thought and knowledge, the development of narrative competence, the classification of different genres of personal narratives, and the structural elements and functions of narratives in the context of human experience and action.

Ethical Principles

As researchers in psychology, narrative psychologists are guided by the ethical principles that different academic and professional psychological associations have formulated based on the usual ethical guidelines for research involving human subjects. In addition, narrative research

on personal narratives has a certain affinity with an Aristotelian contextual-relational conception of ethics, depicting morality as a medium of moral negotiation in terms of mutual understanding, recognition, and responsibility. Articulation of the different concepts of a good life connected to the varieties of narrative configurations of identity is thus seen as a necessary precondition for ethical deliberations, judgments, and agreements. And some narrative research is explicitly aimed at giving voices to (marginalized) people to tell their life stories and at making explicit their view of a good life embedded in their stories, in some cases as a testimony. Stories are generally valued as a medium for ethical reflection. They are appreciated as a resource of moral knowledge related to different historical, cultural, social, and individual contexts and as a fund of articulated values connected to morally relevant life experiences sensitizing people to the responsibilities and challenges of a moral life.

Key Values

Most research in narrative psychology is related to three key values: empowering individuals to have a good life, accepting and sustaining a plurality of life forms, and enhancing mutual understanding between individuals, groups, communities, life forms, (sub) cultures, etc.

Conceptualization

Nature/World

On the one hand, nature is contrasted with culture and conceptualized as all dimensions of human existence and the world not addressed within narrative or cultural psychology. In keeping with this conceptualization, our world is roughly divided into a natural sphere and a human, cultural sphere. The former is more likely to be structured in the paradigmatic mode of logic and science and the latter in the narrative mode of experience and story (Bruner 1986).

On the other hand, narrative psychologists have also distinguished between the human experience

of nature as part of the human world and the everyday lives of people and nature as a concept defined in and for natural science research. Questions such as how people construct meaning in nature through narratives, how they enjoy or fear nature, and how they perceive, experience, and represent natural objects and processes, etc., are part of the narrative study of folk psychology.

Human Being

In narrative psychology, human beings are conceived as beings caught up in stories. Some narrative psychologists insist that human existence is already structured by narrativity, whereas others see human beings at least primarily as tellers of and listeners to stories. The multiplicity of stories and the multiplicity of meaning in narratives reflect human possibilities and the fact that humans' storied lives may inherently be as polyphonic and self-contradictory as stories and their interpretations.

Life and Death

At least in Europe and North America, the (folk) concept of human life is intimately linked to the concept of narration, as we speak of the story of a life to characterize the interval between birth and death. Narrative psychology is connected to this concept and addresses life as meaningful human life evolving diachronically between birth and death. The meanings of life (and death) are related to stories in multiple ways, and narrative psychologists conceptualize, analyze, and interpret these relationships between life as led and life as told, between life and story, and within the conceptual horizon of notions such as life history, life story, (auto) biography, self-narrative, and narrative identity.

Reality

The relationship between stories and reality, especially the relationship between stories and the reality of human experiences, is of great interest to narrative psychologists. Most narrative psychologists argue that the narrative form not only represents but also constitutes social reality and that the reality of human experience has a narrative structure. According to this approach,

reality cannot be conceptualized as a closed material system. Rather, meaning and language are believed to belong to the order of reality. Narratives influence reality as much as they are influenced by reality. The greatest master plots (e.g., the stories of Oedipus, Medea, Cain and Abel, Pygmalion, Cinderella,) are narrativized over and over in literature, art, and even music and have inspired stories, images, spectacles, movies, and other cultural artifacts because they engage desires, fears, and conflicts that seem to be a permanent part of our circumstances as human beings (in the context of Western culture). And these desires, fears, and conflicts are constantly socially shaped and inspired by the cultural and personal stories about them.

Human Knowledge

Much of our knowledge about our everyday, social, and personal life consists of stories, and it is only through narrative that we know ourselves as actors who operate over time.

Truth

Research in narrative psychology can best be related to a consensus model of truth, according to which "truth" depends on uncompelled rational consensus as the result of a dialogue of competent (research) partners, in which specific claims have been critically reviewed according to certain criteria. Additional considerations include the possible evaluation of stories, for example, the distinction between "narrative truth" and "historical truth" in psychotherapy (Polkinghorne 1988; Sarbin 1986). This distinction makes it possible to evaluate a life story as true because it enables someone to live with it (narrative truth) or because it represents life history and facts of the life course adequately (historical truth). Other suggestions are to replace the notion of truth with other criteria for evaluating stories, with criteria such as coherence, complexity, plausibility, verisimilitude, lifelikeness, etc. With regard to "events" or "lives," there is always a plurality of acceptable stories that could be told about them, depending on the contexts, points of view, or interests of the storytellers and the audiences of these stories. Nevertheless, the

notion of truth reminds narrative researchers not to overlook completely the “reference” question (which is relevant at least in some cases) about the relation between particular events, experiences, or lives and particular stories about them: In what manner or to what extent do they represent, reconstruct, or reveal these events, experiences, and lives and how or to what extent do they disguise, distort, or destroy them?

Perception

Wherever we look in this world, we seek to grasp what we see not just in space but also in time, and we are able to do this in the narrative mode. Experiments conducted back in the 1940s have demonstrated how the narratory principle organizes human perception. In these experiments, people were asked to observe geometrical figures in motion and to describe what they saw. The descriptions revealed that people told stories, assigned meaning to the movements of these figures, and described them in narrative terms including activities, intentions, and emotions of humanlike protagonists (Sarbin 1986).

Time

Relying on a distinction between chronological or measured time and human time or experienced time, narrative psychology stresses the close link between narrativity and our experience of time. It is via narrative that we experience time as meaningful, and it is this meaningful experience of time that provides the basic structure of our narratives. As Paul Ricoeur has outlined, the act of the plot (the emplotment or narrativization) distills a meaningful temporal whole from an otherwise chronological sequence of unrelated episodes (Polkinghorne 1988). In other words, the act of plotting elicits a pattern from a succession that at the level of human actions or human consciousness synthesizes attention to the present with expectations for the future and memories of the past. In addition, narrative opens the experience of history beyond one's personal existence. It is especially via narratives that we relate to the lives of former generations, realize the finite nature of our own existence in the face of death, and care for future generations.

Consciousness

In narrative psychology, there are different approaches to consciousness. On the one hand, the concept of consciousness is acknowledged, and narrative may be understood as a primary act of mind or a mode of consciousness. Narrative may also be understood as connecting two landscapes to each other: a landscape of action and a landscape of consciousness entailing what actors perceive, know, think, and feel or do not perceive, know, etc. The combination of these two landscapes requires special narrative inquiry and analysis (Bruner 1986). On the other hand, narrative inquiry is also understood as an alternative to the phenomenological studies of consciousness situating our knowledge, thoughts, and feelings in the realm of practices, activities, and speech actions. This approach replaces the analysis of consciousness with that of narratives as symbolic forms, performances, and practices (Narrative 2006).

Rationality/Reason

Narrative rationality and narrative reasoning are rather popular notions within narrative psychology. Some aspects of human motivation, emotion, or morality may best or may even only be expressed or identified in stories. Storytelling may therefore also be used as a special form of reasoning. We can explain or understand an action by telling a story about it; a good story can be as persuasive and solid as purely formal and logical argumentation. We explain how a particular event became possible by narrating the events leading up to its occurrence. A narrative explanation may also show how the event figures in an intelligible series of events. Narrative reasoning usually does not support predictions but relies instead upon retrodiction to indicate how the present is a possible consequence of the past. It relates more to practical wisdom than to formal intelligence. The wisdom of the biblical King Solomon, for instance, is expressed in stories, and storytelling is very important in mystical movements such as Hasidism.

Mystery

This concept is rarely important within the terminology of narrative psychology. Sometimes, however, stories are understood as a tool to demystify

life and to shape order with regard to one's life experiences. We can also understand mystery as the result of a story and argue that mysteries are narratively produced by explicitly or implicitly failing to meet readers' or listeners' expectations of the normalizing function of narratives, for example, with regard to our expectations of causal order or with regard to the anticipation of closure in conflict resolution or elucidation in response to questions (Abbott 2002).

Relevant Themes

A relevant issue is a concept of experience that is not a synonym for consciousness. Some narrative psychologists prefer an understanding of experience as the act of living through an event or events. Challenging a clear-cut distinction between experience and representation, they focus on the narrative structure of human experiences and discuss adequate methodological concepts to describe, to interpret, or to explain this kind of experiences. Questions arise with regard to the compatibility of different perspectives (e.g., first-person perspective and third-person perspective) and different levels of analysis (from brain activities to socio-cultural contexts). These issues are also involved in debates over the possible links between religion and experience with a special focus on the (social) scientific explanation of particular types of experiences sometimes considered religious, mystical, or spiritual. The question of reductionism has played a pivotal role in these debates. Narrative approaches in psychology of religion valorize cultural and individual diversity and criticize the idea of a common core experience distinguishable from the divergent culturally determined expressions of that core.

Related Terms

[Native American church](#); [Native American spirituality](#)

Description

Any statements about Native American religions must begin with a disclaimer: The religious practices of the indigenous peoples of North America are remarkably varied and have undergone profound changes since contact with

European civilizations. The extent of European colonization upon indigenous American ways of life, thought, and ritual practice are so profound as to render a discontinuity between life before European colonization and life afterward. One thing is clear though, effects on population were vast; it has been estimated that fewer than 10 % of indigenous Americans survived the first century of European presence. This rampant devastation and the perennial conflict that ensued have transformed indigenous American civilizations, the full extent of which it is impossible to assess (Martin 2001).

The summary that follows presents a few themes common among the many tribes of North America. It is a distillation of patterns often present in the hundreds of traditions, whose particularities have been transmitted across generations in distinct ancestral languages. These spiritual legacies represent the local histories and delicately balanced ecological relationships among people, animals, plants, places, and the values that sustain them (Deloria 2003).

As is true of all religions, especially indigenous ones, belief, ritual, and everyday practice are never as standardized as people might be led to believe by reading about them. For Native American religions, variation *is* the standard (Hultkrantz 1987). This variation can be attributed to three basic causes: first, institutional hierarchies, where they exist, are typically weak – there is no Pope in Rome who makes infallible statements *ex cathedra*; second, for the majority of their history, these practices have been based in an exclusively oral tradition – no Bible, Torah, or Qur'an could be consulted to determine a precedent or adjudicate disputes about subtly different beliefs and practices; and third, the ritual specialist depends on his or her own observations and revelations in the elaboration of ritual. These three factors tend to produce religions that are pluralistic and inclusive in nature.

Borrowing from other traditions, responsive to contemporary situations, and expressed in idiosyncratic voices, Native American religions engender a dynamic sensibility that would seem to be at

odds with the conservatism and mutually exclusive character of European faiths. Whether it is due to or in spite of this flexibility, Native American religions demonstrate long-term patterns of practice that are confirmed in the accounts of foreign observers who have recorded similar myths and rituals in different communities over long periods of time (Paper 2007).

Native American religions are composed of oral traditions which could be labeled as sciences in the sense of specialized bodies of knowledge. For instance, myths often encode a robust set of important details regarding tribal history, kinship structures, food production techniques, and features of the terrain. The highly practical and the mythological have always been fused in Native American religions. Moreover, these traditions promote a desire to carefully observe the natural world and all its creatures. Special knowledge as well as information of relevance to present concerns may be found in weather changes, bird songs, and animal sightings. A more restricted definition of science as a form of data collection and hypothesis testing constrained by particular theories and methods does not apply to the kinds of knowledge and ► [revelation](#) typically present in Native American religions. But a deep respect for specialized knowledge and wisdom is seen in these traditions. There is often a guild-like secrecy to promote respect for and protection of such knowledge. In Native American communities religious knowledge often coexists with but is irreducible to scientific knowledge, as is the case in a number of cultures. Many Native Americans are college educated, so scientific knowledge is well represented in tribal settings both on and off established reservations.

Key features present in many Native American religions include the importance of dance and song in ritual performance, a reverence for particular plants, animals, places, and things, the ritual use of tobacco, the importance of the four directions (and fourness in general), respect for and prayers to deceased elders, a reliance on religious experiences rather than faith or the espousal of doctrines, and the use of sweat lodges for purposes of healing and knowledge (Paper 2007). Interestingly, healing

and knowledge are often considered the same thing in these traditions so that medicine can be both healing substance as well as healing power imparted through ► [revelation](#). Other features common to Native American religions, though less appealing, include the appropriation of Native American symbols and rituals by outsiders and the multiplication of self-appointed guides who espouse knowledge of indigenous rituals and often charge high fees to perform them for nonnatives (Paper 2007; Geertz 1994). Perhaps, the most common pattern to be found across these many traditions involves the inextricability of religion from all other aspects of life. A dichotomy such as “science and religion” makes little sense here, as do most other ontological divisions. Ritual, values, practical actions, and knowledge are tied together into a whole such that dichotomies between the natural and the supernatural, man and nature, or the sacred and the profane do not fit well in these indigenous frameworks (Hallowell 2002).

For many Native American groups, authority resides in kinship arrangements so that tribal rule, access to land, and knowledge required for cultivation, healing, and hunting resides in particular families or clans (Geertz 1994). Each tribe may have ritual specialists whose powers to heal and to communicate with divine powers affords them a reputation, and a subsequent demand for their services, that travels beyond local borders. A common title for such specialists has been medicine man though the term shaman has begun to dominate much of the literature. Neither term is satisfactory; the more generic “ritual specialist” is slightly preferable. Both terms were created by outsiders as single labels that typically reduce a wide variety of official and unofficial roles performed by healers, prayer makers, musicians, dancers, and any number of others. However, since these terms are useful enough that even many practitioners use them when speaking about their own traditions, it is fair to use them with the understanding that they always simplify a more complex set of social arrangements and practical expertise.

One of the problems of using single terms (such as Medicine Man or Shaman) is that it

gives the impression that ritual specialists inhabit a singular role in their tribes (“the native priest”), which is not commonly the case. In fact, a more common pattern would suggest that numerous people in a tribe are privy to esoteric knowledge that permits them a specialized ritual role within their communities. Common knowledge might dictate that one should visit a certain person for the treatment of wounds, a different person for intestinal distress, another for hunting success, someone else for the undoing of curses, and so on. The knowledge that ritual specialists receive may be taught by others or it may be learned by ► [revelation](#), imparted through dreams or during ritual fasts. Additionally, it is through the performance of elaborate rituals that many people experience religious insights of importance to themselves and their communities. In short, direct experience through ► [revelation](#) is the most common source of authority in Native American religions.

However, it is often the case that consensus rules the day, here as elsewhere in tribal settings. If a person has a ► [revelation](#) of importance to the group, it is only effected on a group level if a consensus is reached about the meaning and significance of it. This is rather like the “summing up” of news and information in any group setting: perhaps one member of a group has heard from an outsider that a foreign army is headed in their direction. Such news will not typically cause the community to ready itself for invasion unless others have also confirmed this or decided it is prudent to make tentative preparations.

Native American religions emphasize such basic values as respect, obligation, and harmony. Whatever is received must be reciprocated in some fashion; many of the rituals are based on this principle. Family unity is central to the ethical principles of this tradition. From family unity, an ethic of respect and reciprocity ensues so that elaborate covenants and duties have come to exist between children and parents, humans and nature, individual and community, the living and the dead. This background of reciprocity leads to complex notions of equilibrium and harmony between all things that sustain life. Ideas

about kinship typically extend well beyond the family to include virtually every other entity involved in the set of life-giving relationships. Animals, plants, sources of water, features of the terrain, and the sun may be addressed and attended to ritually as kin relations. An omnipresent sociality exists between the person and many things in the human and nonhuman world. Clan, family, or personal obligations to particular kinship relations over others underlies the powers and knowledge that ritual specialists may possess.

The term animism has been used in the past as a categorical framework applied to many indigenous peoples. Animism is the idea that the entire world is “ensouled,” that is, each and every thing has a soul in the same way that a human being is thought to possess one. For the most part, this means that stones, plants, and places have human-like minds filled with knowledge and desires. In very blunt fashion, this is a reasonable generalization to apply to Native American religions but, as with such labels as medicine man and shaman, it is an outsider’s term that unfairly reduces much more complex realities. In a given tradition, some places and things may possess “spirits,” while others may not (Hallowell 2002). Moreover, some things may be ensouled for certain periods (like during a ritual), but not at other times. And while any number of things may be special in this way, some are differentially more important or powerful than others. Part of the knowledge that a ritual specialist possesses is being able to identify which things are animated and/or needful and which things are not. So while animism captures some of this in a general way, it should not be relied upon as reification applicable to all the particular practices and understandings within a tradition.

Context plays an important role in Native American religions so that the relative truth and importance of knowledge and practice can change in response to other revelations and may only apply in certain places. In a sense, only the local matters and there is little interest in the “universal.” However, this precedence of the local over the global, of “our people” rather

than “all people,” has shifted because of the modern realities that connect everyone as well as the increasing role that universalizing influences such as Christianity play in Native American religions. An originally Jewish tradition with scriptural roots that extend back more than 3,000 years, Christianity is particularly global which has led it to emphasize a universalizing metaphysics. Native Americans encountered Christianity almost as soon as they encountered European colonists but conversion has been slow. Over the centuries, Christian missionaries have attempted to convert Native Americans at the point of the sword and in the comfort of embrace. Whatever the particular dynamics, it is now common for Native American religions to include Christian ideas and practices (Martin 2001). Christ or Christ-like culture heroes may be recounted in seemingly old myths and it is perfectly normal for a Native American to perform a basically indigenous ritual and then go off to celebrate Catholic Mass.

Peyote religion, sometimes but not always practiced under the auspices of the ► [Native American Church](#) (one of several related denominations), also espouses a global rather than local perspective. The use of peyote (A psychotropic cactus, *Lophophora williamsii*) for ritual originally came from indigenous groups in Mexico but was adopted by Native American groups in the United States during the late nineteenth century (Hultkrantz 1987; Paper 2007). Peyotism has been supported by and supportive of ► [Pan-Indianism](#) since it spread rapidly across numerous reservations in the late nineteenth century and incorporated a variety of rituals and prayers from these different settings. Christian ideas and influences are often central to these practices.

Native American religions consistently demonstrate a deep respect for the ecological relationships in which they are involved. An enduring interest in the natural world has produced a sophisticated knowledge of plants, animals, and other phenomena. Native American religions have imparted uniquely ecological patterns into their practices: people, costumes, prayers,

objects, foods, and dances are carefully orchestrated at special times and places, for the performance of ritual.

Contemporary scientific knowledge and practices employ a metaphysical framework and epistemology often at odds with those of Native American religions. While science critically depends upon empirically derived evidence for the purposes of knowledge production, Native American religions differentially emphasize ► [revelation](#) as a means of the acquisition of knowledge. Nevertheless, systematic observation, the use of inductive logic, and the amassing of data apply equally well to many forms of science and Native American religions.

Description

The field of Native American Studies (NAS) emerged out of the intense political activism of the 1960s and 1970s, and the number of programs at US and Canadian universities has grown considerably over time. Since the emergence of NAS as a distinct study area, there have been ongoing discussions among *NAS* scholars about the nature of this field of study. Should *NAS* be a distinct department within colleges and universities, or is the strength of *NAS* in its strong interdisciplinary approach and ability to penetrate and critically engage many academic disciplines? Additionally, there is a strong sense of purpose in much *NAS* scholarship that intellectuals, both American Indian and non-Indian alike, should hold themselves accountable to the communities from whence they come and/or in which they work. Not only should *NAS* scholarship hold itself accountable (and be held accountable) to American Indian and First Nations communities, many scholars believe that *NAS* should be defined by a clear articulation of the enduring sovereignty and nation-to-nation political status of American Indian and First Nations communities and a clear expression of the inherent rights of and responsibilities of indigeness.

Various American Indian nations were the subject matter of study in ethnographic writings of early missionaries, such as the Jesuits and in the travelogues of European explorers. When

Native American Spirituality

- [Native American Religions](#)

anthropology emerged as a formal discipline in the nineteenth century, most indigenous cultures were studied, analyzed, and theorized about within anthropological discourse and its related disciplines. This body of literature about American Indian people was and largely remains a Western intellectual pursuit, applying the accepted methods and theories of anthropology proper and of the social sciences in general. Either the meta-values of the Western academy or the meta-values of one form of Western political ideology or another have largely dominated anthropology and the social sciences. That is simply to say that the humanities, as currently practiced in universities, are almost entirely a Western epistemological endeavor.

In contrast, NAS scholars operate from the understanding that emic perspectives are most appropriate when studying a particular cultural group. Emic reflects an insider's perspective, in contrast to the ostensibly objective and disinterested observer's perspective. Much of anthropology, sociology, and religious studies has occurred from an etic, that is, outsider's or exogenous perspective. In contrast, Native American Studies has advocated strongly for the validity, authority, and appropriateness of the emic perspective. In other words, one of the founding ideas behind NAS as a distinct field of study is that where the cultures, traditions, ceremonial lives, and histories of American Indian people are concerned the authority and expertise rests firmly with the people themselves. To nuance this a little bit further, there is no consensus that *only* American Indian people should write or speak about American Indians. In fact, even though the distinctive qualities of NAS come from the fact that its foundations are based squarely in American Indians speaking and writing for themselves and insisting on the appropriateness and value of doing so, there is much quality scholarship in NAS produced by non-Indian intellectuals.

The generation of American Indian intellectuals that created NAS provided a powerful voice within the academy for American Indian scholars to speak and write from a native perspective that has persisted and grown. NAS has also prompted

critical self-reflection by non-Indian academics in various academic fields: anthropology, history, English, political science, religious studies, and the humanities in general. This is a powerful development because as American Indian scholars have put forth a more and more powerful and compelling voice within the academy, all facets of the social sciences have been impacted. Powerful critiques have developed with a focus on gender, sexuality, two-spirit people, alternative spiritual conceptions of the world, the impact of missionization on indigenous communities, "kinship cycles of responsibility," deep structural differences between the world views and epistemes of Western and indigenous cultures, and assessments of the globalization of capital and its impact on indigenous communities.

There was an epistemological shift advanced by American Indian scholars and activists that insisted that the cultures and experiences of indigenous people should have both primary and secondary authority and value within the academy and society and large. Scholars and activists, such as Vine Deloria, Jr., Alfonso Ortiz, Beatrice Medicine, Elizabeth Cook-Lynn, Ines Talamantez, George "Tink" Tinker, and John Mohawk have argued that American Indian culture carriers and intellectuals can and should articulate their own peoples' perspectives and traditions to the larger society rather than being named, identified, and analyzed by non-Indian scholars. Though Vine Deloria, Jr., was certainly a grandfather of NAS in this regard, a fact acknowledged by many contemporary American Indian intellectuals, it is important not to forget the earlier generations of American Indian people that were a voice from both their own nations and of American Indians in general: Ella Deloria, Francis LaFleche, Charles Eastman, Luther Standing Bear, and many others.

NAS as a specialized area of study has largely grown as an interdisciplinary field, and there are now well over 100 degree programs, majors, minors, and certificate programs in NAS (includes American Indian Studies and Indigenous Studies programs) at US and Canadian universities. NAS has developed along three

important lines. First is the growth of literature about specific American Indian cultures written by people from those nations and communities. Second, critical discourse around issues either broadly or universally faced by indigenous communities: reassertion of national sovereignty by indigenous nations, the ongoing reality of colonialism as faced by American Indian people and their respective communities, studies of American Indian contributions to the development of both the United States and other settler nations, the history of missionization and cultural genocide faced by most indigenous peoples. Third is the articulation of those common, if not absolutely universal, characteristics of American Indian cultures and societies. This third line of development in NAS has led to important articulations of indigenouness or indigeneity and has provided important intellectual foundations for solidarity and resistance by people who self-identify as not only part of their own specific communities but as part of the broader "American Indian" community and sometimes described as a ► [Pan-Indian Movement](#).

NAS has offered a provocative and thoughtful contribution to the academy by articulating epistemological and philosophical systems that challenge some of the fundamental assumptions and mechanisms of the social sciences, the physical sciences, and the increasing hegemony of American economic, political, and cultural systems. Sometimes implicitly and often explicitly, NAS scholars have provided very timely and fundamental challenges to the status quo in demanding a fair consideration of traditional knowledge, holistic indigenous sociocultural systems, complex economic systems, and the distinct ritual and ceremonial systems of indigenous peoples. These challenges often have cut to the heart of key cultural differences regarding how human beings construct and organize their experiences and thoughts. In this sense, within the dialogue between science and religion, many *Native American Studies* scholars have challenged the fact that these areas of knowledge are considered distinct in the Western intellectual tradition. In many cases, critiques leveled by

Native American Studies scholars have not been simply a rejection of the empirical data of the Western academic traditions but rather of the inadequacy of contemplating information outside the context of the life of the community, the ongoing well-being of one's "relations" and outside the corpus of stories, and ritual and ceremonial life of the people. Scholars and linguists, including Albert White Hat, Sr., have pointed out that in most (if not all) American Indian nations, there is no word that properly translates as religion, which minimally suggests that hegemonic Western binaries of religious/secular, faith/knowledge, and religion/science do not prevail or even obtain in many indigenous societies and their knowledge traditions.

Among the more prominent journals devoted solely to NAS are *Wicazo Sa Review*, *The American Indian Quarterly*, and the *American Indian Culture and Research Journal*.

Natural Language Processing

Vasile Rus

Department of Computer Science,
The University of Memphis, Memphis, TN, USA

Description

Natural Language Processing (NLP), also called Computational Linguistics, aims at developing computational methods and algorithms for understanding and generating human languages. There is a clear delimitation between the camp that deals with understanding of language, which is called Natural Language Understanding (NLU), and the camp that addresses issues with respect to generating or producing natural language, which is

called Natural Language Generation (NLG). The NLP field has been dominated by the NLU camp from its early beginnings in the 1950s until now, with little prospects of a more balanced representation in the near future between NLU and NLG camps. The dominance of the NLU camp can be explained by at least two factors. First, there has been a desire in the Computer Science domain to make computers understand human language. Second, language generation is perceived harder, from one perspective, than language understanding.

The NLP field can be divided into many subfields based on the many aspects of human languages. Morphological processing is the subfield studying how individual words are formed from the smallest units of meaning called morphemes. Lexical semantics is the subarea of NLP dealing with the meaning of individual words in isolation, that is, not in context such as in a sentence. The subfield of syntactic processing explores how words group together in larger constructs, such as phrases, and ultimately as entire sentences. Semantic processing deals primarily with capturing the meaning of individual sentences, while discourse processing looks at how sentences group together in larger chunks of language, called discourse, such as paragraphs and documents.

Due to the explosion of the World Wide Web during the past 2 decades and of electronic storage of documents on personal computers and various organizations' servers, there has been a lot of activity in the applications of NLP to solve various real-world problems. The best example is the web search application in which the task is to retrieve a ranked list of documents relevant to a user-specified query. Among other applications that need Natural Language Processing are Question Answering, Intelligent Tutoring Systems, Summarization, and Text Mining.

Self-identification

Science

Natural Language Processing is a science in which the many theories about how humans

process language or how language must be processed, in general, at different levels (morphological, syntactic, semantic, and discourse) are empirically tested. Outcomes of various models are compared with either human-expert judgments or with less subjective judgments, for instance, performance on a specific task.

Characteristics

Natural Language Processing focuses on developing methods and computational algorithms for understanding and generating language. No other discipline has these goals as its primary concern. Speech Processing is a different, although related, discipline. Speech Processing should not be confused with Natural Language Processing. The goal in Speech Processing is to map an audio representation of language into an electronic written representation, that is, text. As language is closely related to logic and reasoning, domain and world knowledge, and intelligence, Natural Language Processing benefits and helps the discipline of Artificial Intelligence to fulfill its goals of building intelligent entities.

Relevance to Science and Religion

There seems to be little interest in “Science and Religion” among computational linguists, that is, people working in the area of Natural Language Processing. Religious implications of the discoveries in the field of NLP are not systematically studied and published by the community at large.

Sources of Authority

A number of conferences and journals in this area are the authority that validates findings reported by researchers. A rigorous peer-review process enables a democratic-based authoritative regime in the field of Natural Language Processing.

Ethical Principles

Standard scientific evidence-based research seems to be the driving force in the field of Natural Language Processing. Theories validated experimentally through repeatable experiments are the appropriate processes to be successful. Authors are required to present their methods in such a way that someone else reading their report could reproduce the experiments and results.

Key Values

The key values are investigative spirit, creative minds, honesty, pushing the limits of our current understanding of how humans understand and produce language, and how language is connected to other parts of the human mind and our perception of the world.

Conceptualization

Nature/World

Language is a communication means that is used to communicate/share knowledge about the world for the ultimate purpose of better acting in the world. There is no implicit assumption about the world in the Natural Language Processing community. Language is viewed as the vehicle that could be used to share any view of the world as perceived by the speaker, that is, producer of the language.

Human Being

Humans are viewed as rational beings, who produce language with a purpose/goal.

Life and Death

There is no particular view with respect to life and death that is debated in the Natural Language Processing community.

Reality

Language understanding and generation is highly dependent on world knowledge. Spatial and

temporal laws are used to find the correct interpretation of human language utterances.

Knowledge

It is the body of concepts and relationships among concepts that could be used to arrive to a correct interpretation of an utterance that uses these concepts. Correctness is defined as a verifiable true fact.

Truth

Truth is a body of facts consistent with reality. An event is true with respect to reality if it can be shown experimentally that it does conform to the facts in reality. The experiment can be repeated as many times as one wishes and must always lead to a result consistent with reality. That is, the fact should always produce other aspects of reality which are directly measurable as proof of the truth of the fact being studied.

Perception

All measurements/experiments in Natural Language Processing are limited by their nature. That is, the set of all possible sentences humans could produce is theoretically infinite. Any theory that is being tested will never have access to the whole set of human language sentences to fully validate the theory.

Time

Time is the always increasing dimension of the world we live in. Implicitly, when humans generate language there is a chronological sequence in which a word at the beginning of a sentence has been clearly generated before a word at the end of a sentence. This implicit chronological order of words in a sentence is different from the time dimension of the reality the sentences are describing. That means that a fragment of language could describe a story that has happened at another time, in the past or future, with respect to the time the speaker generated that language fragment.

Consciousness

Language and mind are tightly connected. The interplay between language and

consciousness is not of a primary concern at this moment in the field of Natural Language Processing. The related field of Psycholinguistics may study that relationship more actively.

Rationality/Reason

Logic and Reasoning are closely connected to human language. There is much research that looks at how language and reasoning interact. Making inferences on knowledge encoded in natural language is a hot topic in Natural Language Processing.

Mystery

Natural Language Processing is a quite technical field focusing on understanding the obvious, as opposed to mysterious, aspect of language. However, there is work on metaphor, humor, sentiment analysis, and other more mysterious aspects of human language.

Relevant Themes

The field of Natural Language Processing has grown significantly in the applications aspects of it. There are research groups in various fields with an interest in Natural Language Processing without really doing basic research in this area. The following is a list of such fields that are paying more and more attention to NLP: educational technologies/intelligent tutoring systems, biotechnology, finance and economics, intelligence community, software engineering, and medicine.

Natural Religion

► Deism

Natural Sciences in Judaism

Norman Solomon

The Oriental Institute, Oxford University,
Oxford, UK

The familiarity of names such as Freud, Einstein, and Feynman is evidence that since the latter half of the nineteenth century Jews have been at the forefront of scientific advancement. But do the extraordinary achievements of individual Jews reflect anything of the value placed by the Jewish *religion* on enquiry into the nature of the physical world? Is there any *organic* connection between Jewish thought and scientific discovery?

In looking back through time we must be aware that the concept of “natural science” as understood today is a product of the modern era; only relatively recently have the sciences, as organized observational disciplines, separated on the one hand from philosophy and on the other from religion or magic.

We must also make clear what we understand by “Judaism,” since the forms of Judaism encountered today are not identical with the religion of ancient Israel as depicted in the Bible. The “classical” period of formation of Judaism is that of the sages, or rabbis, whose views are recorded in the Talmud, a compilation of teachings from roughly the first to the sixth

century; this tradition was further developed in the Middle Ages and underlies most modern interpretations of Judaism.

Depending on how “religion” is understood, it could be misleading to categorize “► [Torah](#),” the Jewish tradition, as a religion, since it encompasses far more than “spiritual” issues. Most forms of contemporary Judaism accord special status to halakha, usually translated as “law,” but overlapping with ethics and morality; in many periods what we now call “natural science” has been understood as knowledge of God’s creation and therefore intrinsic to the religious tradition. In this entry we review the evolution of the relationship between Jewish tradition and natural science, noting different areas in which they have interfaced.

Though various personalities have from time to time, or within specific sects, been regarded as authoritative, there is nobody or individual today with overriding authority in the Jewish religion. Bible, Talmud, and medieval authorities such as Moses Maimonides (1138–1204) are regarded with respect, but not necessarily as determinative; consequently, there can be no definitive statement of the Jewish position on natural science.

Bible and Natural Science

While this entry is primarily concerned with rabbinic attitudes to science, a brief glance at the Bible (“Old Testament”) will supply a necessary background. The Hebrew scriptures, in contrast with Christian and later Jewish sources, do not on the whole support a dualism of body and spirit, and certainly do not disparage the material world. In the opening chapter of Genesis nature – that is, the material world – is affirmed as God’s creation, therefore good; this attitude is fully borne out in hymns such as Psalms 104 and 148.

The Bible generally takes for granted that the world was designed and created by God, and that it is run by God who every now and then intervenes directly to make sure that His purposes, for instance, redeeming the Israelites

from Egypt, are fulfilled. The underlying assumption is that phenomena and events in the world are the result of design. This assumption harmonized well enough with Aristotelian science, which was teleological, but has been increasingly questioned by philosophers since Descartes, and is no longer a useful scientific hypothesis (which is not to say that it is false). The concept of an intervening God ready to suspend natural law to save His people runs counter not only to mechanistic science but scarcely less so to the probabilistic science of the twentieth century; from quite a different angle it was undermined also by reflection on the Holocaust.

The Bible's hostility to magic and witchcraft (e.g., Deuteronomy 18:10) does not necessarily denote denial of the reality and efficacy of supernatural processes. The account of Creation in Genesis 1 omits all reference to demons and other nonnatural beings; this certainly denies their significance and perhaps denies their existence, though the existence of both angels and demons is acknowledged elsewhere in scripture.

The Bible expresses appreciation of the order and beauty of the natural world and of the power and wisdom of its creator. Job, with numerous illuminating references to natural phenomena, is primarily descriptive, as in Chap. 28 on mining, and Chaps. 38–41 where God overwhelms Job with awesome descriptions of everything from the crocodile to the Pleiades. Other biblical passages bear evidence of systematic thought about nature, including attempts to classify and evaluate phenomena and their relationships (Feliks 1981). Genesis 1, for instance, sets out a well-ordered, hierarchical scheme of creation; a carefully devised classification of the natural order underlies the ordered lists of birds, beasts, and sundry creatures in Leviticus 11 and Deuteronomy 18; likewise, there is a systematic description of “leprosy” in Leviticus 13 which can only be the result of reflection on the results of careful and extended observation of skin lesions.

The relationship between science and religion in the Bible is not a relationship of distinct disciplines, for the Bible does not clearly separate science and religion; all knowledge is presumed to come from God.

The Talmudic Period

Since the late nineteenth century, several studies have been made of natural science, especially medicine, and of mathematics in the Talmud and later rabbinic writings (Feldman 1931); more recent scholarship has modified these pioneering accounts in the light of new ideas on the formation and interpretation of both classical and rabbinic texts.

The rabbis of the Talmudic period treat natural science as ancillary to religious purposes. They believed that scripture was both inerrant and comprehensive, in that it contained all knowledge and was the source of all truth, so they insisted that knowledge of created things was divinely revealed, and that other nations had “borrowed” it from the Jews. The third-century Palestinian Rabbi Yohanan interpreted the verse “For this is your wisdom and understanding in the eyes of the nations” (Deuteronomy 4:6) with reference to Jewish pre-eminence in astronomical calculation (BT *Shabbat* 75a); medical remedies were said to be recorded in the book of cures concealed by Hezekiah, King of Judah, hence of “Jewish” origin; while “facts” of nature are frequently read into biblical verses (Lieberman 1950).

In fact, the rabbis' observations on nature are rarely original and not always sound; Jewish physicians, of whom little is known until after the close of the Talmud, followed Galen rather than “rabbinic” medicine (Lieber 1984). In the early modern period cosmology proved embarrassing to those who wished to defend rabbinic tradition. Other elements of rabbinic natural science were not known to be erroneous until more recently. For instance, lice were said not to ‘be fruitful and multiply’, implying that they were generated spontaneously from sweat or dirt; fleas, on the other hand, were fruitful and multiplied (BT *Shabbat* 107b). Such opinions were in keeping with the science of the time – spontaneous generation was not discredited until the time of Pasteur – but since they are embedded in texts carrying religious authority they generated conflict between science and religion.

The third century Babylonian teacher Shmuel had a reputation for eye salves (BT *Shabbat* 108b), and asserted that he knew remedies for all bad

eating habits except three (BT *Bava Metzi'a* 113b); he declared: "The paths of heaven are as familiar to me as the streets of Nehardea" (BT *Berakhot* 58b). As he left no pharmacopoeia, no star atlas, nor a map of Nehardea, it is impossible for us to assess these claims. His calculation of the *tekufa* – the average period between solstice and equinox, or precisely a quarter of the solar year – is 91 days and 7½ h (BT *Eruvin* 56a); this coincides with the length of the Julian year and is inaccurate, hence the Jewish festivals now occur on average almost 2 weeks later in the year than they should. A more accurate figure, of 91 days 7 h 28 min 51.34 s, was attributed by Jewish scholars from about the tenth century to Shmuel's contemporary Adda bar Ahavah; this value is close to that given by Hipparchus in the second century BCE, but it is not mentioned in the Talmud, and the link with Adda bar Ahavah seems spurious.

The 19-year cycle on which the Jewish liturgical calendar is now fixed, effectively harmonizes the solar and lunar calendars. Outside rabbinic literature, it is known as the Metonic cycle, after the fifth century BCE Greek astronomer Meton who calculated it; the Babylonians had been following this cycle from at least 500 BCE, but it is not mentioned in the Talmud.

The Babylonian Talmud contains several collections of remedies introduced by the third century teacher Abbaye with the words "my mother told me" – an attribution to be taken not at its face value but as editorial semantics for "popular tradition." Some of the remedies are common sense, as for instance to turn the seam of a baby's swaddling cloth outward so as not to injure him (BT *Shabbat* 134a); others concern the formulae and repetition of spells (BT *Shabbat* 66b); many are to do with diet (BT *Ketubot* 10b) or the correct use of plants and herbs. Numerous Hebrew amulets and incantation bowls from the first to fifth centuries have been recovered and studied by archaeologists; many of them were written by non-Jews evidently hoping to capture the efficacy of the "Jewish magic" which was held in high repute in late antiquity (Naveh and Shaked 1998).

Demons, possession, and the evil eye – the first rare and the latter two absent from the

Hebrew scriptures – figure commonly in rabbinic literature (Schäfer 1990; Schiffman and Swartz 1992; Trachtenberg 1939).

Julius Preuss (1861–1913) (1978) pioneered the discussion of Talmudic anatomy and physiology. The Talmud lists the parts of the body in connection with laws of ritual purity (Mishna *Oholot* 1:8), and enumerates defects which would render priests or sacrificial animals unacceptable for Temple service (Mishna *Bekhorot* 6 and 7), or render an animal or bird impermissible for consumption (Mishna *Hullin* 3); such knowledge of physiology as it preserves has to do with matters such as childbirth and sexual relations which are regulated by the law. The Talmud is concerned not with the art of medicine per se, but with the *halakha*, or law, and has preserved only those elements of medical science that are needed for correct interpretation and application of the law.

The Middle Ages

The subordination of science to *halakha* was challenged by a number of mediaeval Jewish philosophers, foremost among them Bahya ibn Pakuda (eleventh century Spain), who adopted the Biblical concept of nature as testifying to the greatness of God as creator and stressed that the study of nature per se led to faith in its infinitely wise Maker (*Duties of the Heart* Vol. 1: 2:1–6). Maimonides similarly derived a duty to study natural science from the command to love God, the creator of nature. Science, that is, was no longer ancillary to religious law, but an end in itself, part of the contemplation on the divine mystery which to Maimonides was the ultimate human felicity; *halakha* was but a propaedeutic to this higher study. He observed, moreover, that the astronomy of the rabbis was neither accurate nor authoritative, since mathematics was not fully developed in their time and their statements on these topics did not derive from prophetic revelation. His son, Abraham Maimonides, articulated the position even more clearly:

It does not at all follow that because we bow to the authority of the sages of the Talmud in all that appertains to the interpretation of the Torah in its

principles and details, we must accept unquestionably all their dicta on scientific matters, such as medicine, physics, and astronomy . . . We ought to be quite prepared to find that some of their statements coming within the purview of science, are not borne out by science of our times. (*Kifaya al-Abadi*)

In an outspoken letter he wrote in 1195 to the rabbis of Montpellier, Provence, Maimonides denounced astrology as a pseudoscience, claiming that he had carried out empirical tests on various astrological theories; he had already formulated a more general rejection of pseudosciences in his code of law, the *Mishneh Torah*:

And all these matters (sc. astrology, necromancy etc.) are falsehood and deceit, by means of which idolatrous priests in ancient times misled the people of the nations to follow them. It is not fitting that (the people of) Israel, who are wise and learned, should be attracted by such nonsense or entertain the possibility that there is any benefit in it. (Laws of Idolatry 11:6)

Medieval cosmologists speculated whether the universe was created in time, or whether it was co-eternal with its creator. Both Saadia (882–942) (*Book of Beliefs and Opinions* Part One) and Maimonides (*Guide for the Perplexed* 2:13 f.) devoted major sections of their principal philosophical works to establishing the former. Maimonides endorses belief in creation in time since reason does not contradict it and it is the plain sense of scripture; had reason led him to believe that the universe was eternal he would have reinterpreted scripture accordingly (*Guide* 2:16 and 2:25).

Jews contributed to the transmission of Arabic-language science to scholastic Europe, and hence to the Renaissance, by means of their translations and commentaries in Hebrew or Latin of the Arabic translations, commentaries, and compilations of Ptolemy's *Almagest* and of other scientific works (Steinschneider 1893). They also engaged in independent astronomical research and observation. The "Alphonsine Tables" were prepared in Toledo for King Alfonso X of León and Castile under the direction of the Jewish astronomers Yehuda ben Moshe haCohen and Isaac ibn Sa'id, the latter a keen observer of lunar eclipses; completed in 1252,

they were based on the geocentric Ptolemaic theory, and enabled astronomers to calculate eclipses and the positions of the planets for any given moment; they were an important source of information for Copernicus, whose own work superseded them in the 1550s.

In 1310, Isaac ben Joseph Israeli composed *Yesod Olam*, a study of astronomy and cosmography, incorporating an original method for calculating the parallax of the moon. Gersonides (Levi ben Gershon, or Ralbag) (1288–1344), in his philosophical treatise *Milhamot Hashem* ("Wars of the Lord"), influential through its (partial) Latin translation, explains in detail (a) his discovery, or improvement, of the cross-staff, a device for measuring angles and spherical distances, which became known in Europe as *baculus Jacobi* (Jacob's staff); and (b) his method of passing a light ray from a star through a small aperture in a darkened chamber on to a board – perhaps a novel use of the *camera obscura*, with which Roger Bacon had recently experimented; his observations led him to question some of the basic assumptions of the Ptolemaic system.

The Spanish-Jewish philosopher Hasdai Crescas (1340–1410) was another pioneer of the scientific revolution, associated with the same movement as Nicole Bonet, Thomas Bradwardine, and Nicole Oresme (Harvey (1998), 3). In *Or Hashem* ("The Light of the Lord") (1410) he concedes the eternity of the world, and elevates natural causality at the expense of human free will; more significantly from a scientific point of view, he rejects Aristotle's proofs of the impossibility of an infinite magnitude, an infinite place, or a vacuum, his definitions of time and place, and the contention that natural motion is a consequence of the four elements seeking their proper places. The most revolutionary aspect of Crescas' natural philosophy is his assertion that the heavens and earth are subject to the same system of natural law (Wolfson 1929, 118–121). Crescas was read by Pico della Mirandola and directly influenced Spinoza; some of his ideas are similar to those for which Giordano Bruno was burned at the stake.

Jewish inventors of astronomical instruments in the later Middle Ages include Jacob ben

Machir, who invented an improved quadrant (an angle-measuring device); Isaac ben Solomon ben Zaddik al Hadib, who invented a new instrument which was a combination of astrolabe and quadrant; Jacob (Bonet) de Lattes (fifteenth to sixteenth centuries) designed a device in the shape of a ring for measuring the height of the sun and the stars; further refinements of the astrolabe were made by Abraham Zacuto (1452–1514) (Cooperman 1983).

The earliest known medical works written by a Jew are the Arabic treatises of Isaac Israeli (c855–955). The *Book of Asaph* or *Book of Healing*, of which several versions exist, is cited in some form perhaps as early as the tenth century, but Asaph ha-Rofé (Asaph the physician), the supposed author, to whom a version of the Hippocratic oath subsequently in use by Jewish physicians is attributed, cannot be identified. This book (manuscripts vary), wrote Richard Gottheil in his article on Asaph in the 1905 *Jewish Encyclopedia*, contains “treatises on the Persian months, physiology, embryology, the four periods of man’s life, the four winds (*sc.* humours), diseases of various organs, hygiene, medicinal plants, medical calendar, the practise of medicine, as well as an antidotarium, urinology, aphorisms, and the Hippocratic oath”; it draws not on the Talmud but on “the books of the wise men of India” and a “book of the ancients”; it ascribes the origin of medicine to Shem, son of Noah, who received it from angels. The contents show dependence on Galen, Hippocrates, and Dioscorides, indicating that the practice of Jewish physicians was modeled not on rabbinic sources but on “scientific” medicine (Melzer 1973). Opinions vary as to the originality of Jewish contributions to medicine, but there is no doubt that Jews played a significant role in the transfer of ancient Greek medical knowledge, together with later Islamic insights, to the West during the Renaissance.

If it is not God’s will to heal us, then by utilizing the art of medicine to heal ourselves are we not thwarting his will? Some Karaites (a Jewish sect who rejected the rabbinic tradition) objected on religious grounds to the practice of medicine. Likewise, Nahmanides (1194–1270) held that God would protect from sickness any

individual who served him in complete faith, and that ideally the sick person should turn to repentance, not to doctors, even though the Torah granted “permission for the doctor to heal” (*Commentary* on Leviticus 26:11). However, the predominant Jewish view is that the practice of medicine is not only permissible but virtuous. Joseph Karo (1488–1575), in his *Shulhan Arukh*, the most influential Code of Jewish Law, states, “. . . [to heal] is a positive obligation, tantamount to the saving of life, and one who avoids doing it sheds blood, even though there is someone else available to [effect the cure], since the patient does not respond equally to every doctor”; one may practice medicine only if duly authorized by a Jewish religious court. Even those unable to perform medical or nursing services are obliged to visit the sick and to pray for their welfare; and intercessions are made publicly in the Synagogue (*Yore Deah* 236:1; 235:10).

By being subsumed within the *mitzvot*, or divine commandments, the practice of medicine becomes part of the spirituality of Judaism. Nevertheless, the specific remedies used by the physician are not determined by the religious tradition itself, but by the independent science of medicine.

Natural Science in the Early Modern Period

André Néher (1986) has shown the extent to which Jews such as David Gans were in direct contact with Kepler and other leading scientific minds of the sixteenth century. Ephraim Kupfer argued that there was a strong current of rationalist culture and philosophical activity among German Jews in the late fourteenth and early fifteenth centuries, and that this stimulated similar interests among Polish Jews in the late sixteenth century. David Ruderman rightly observes, however, that the distinction between physics and metaphysics was a new feature of sixteenth-century Jewish thought, reflecting an emergent consensus in Christian thought on the relationship between science and faith (Ruderman 1995, Chapter 2).

On May 24, 1543, on his death bed, Nicholas Copernicus received the first printed copy of his

De revolutionibus orbium coelestium, completed 13 years earlier, in which he demonstrated the mathematical elegance of calculating heavenly motions on the assumption that the Earth orbited the Sun. To what extent did Copernicus' revival of Aristarchus' heliocentric conception of the universe disturb traditional Jewish thought? Certainly, it was some time before the Copernican theory gained acceptance; as late as 1616 the Inquisition condemned Copernicus' book, and Galileo was tried in 1632. As knowledge of it spread, two problems presented themselves. The obvious one was that, in purely mathematical terms, it contradicted the Ptolemaic theory, which by this period had been incorporated into Jewish as well as Christian theology.

However, what was in the long run far more serious was that it implied, as Crescas had suggested, that the stars and other "heavenly" bodies constituted *one physical system* with the Earth; the heavens were dethroned – in Max Weber's term, "disenchanted." The whole mediaeval fabric of the "chain of being" leading down from the One, through the heavenly spheres, to the Earth and its lowly inhabitants, collapsed. No longer did it make sense to speak of a God who lived, literally, in the sky, or of "eternal life" situated in the heavenly realm.

Conservatives such as Maharal (Judah Loew ben Bezalel: 1525–1609) – one of the earliest to refer to Copernicus in a Hebrew work – remained faithful to rabbinic, that is Ptolemaic, cosmology; he nevertheless vehemently attacks Maimonides' contention that the spheres are intelligent beings (second Preface to *Gevurot Hashem*), thus perhaps yielding to the pressure for "disenchantment." In the same passage he expounds his "double truth" theory that the plane of spiritual reality, though generally synchronized with that of physical reality, occasionally departs from it, as in miracles such as the Sun standing still for Joshua; the "true," spiritual Sun stopped, but the "mere" physical Sun continued on its course.

Maharal's disciple David Gans (1541–1613) was a colleague, or at least acquaintance, of both Tycho Brahe (1546–1601) and Kepler (1571–1630). In *Nehmad ve-Na'im* (1613) Gans offered the first Hebrew exposition of the

Copernican system; like Kepler himself he rejected its substantive implications, regarding it only as an elegant mathematical device, and thereby avoiding any clash with religious tradition.

The Cretian polymath Joseph Solomon Delmedigo (1591–1655), a pupil of Galileo, was the first Hebrew writer to use logarithms; in his *Elim* he expounds the works of al-Battani and Copernicus, apparently endorsing the latter. Tobias ben Moses Cohen, known as Tuviyyah ha-Rofé (1652–1729), "the physician," in his *Ma'aseh Tuviyyah* (Venice, 1707–1708), reviews the heliocentric view but rejects it, principally on religious and traditional grounds, denouncing Copernicus as the "first-born of Satan."

Among the descendants of the *converso* Jews (forced converts to Christianity) who remained in Spain after 1492 and Portugal after 1497 were many who achieved eminence in medicine; most notable was the anatomist Amatus Lusitanus (1511–1567), celebrated for his work on *materia medica* and for his discovery of the function of the heart valves.

Ruderman (1995, 276–285) specifies two areas which constitute a "specifically *converso* contribution to scientific discourse both within the Jewish community and beyond it":

1. Francisco Sanchez (1551–1623), whose *Quod nihil scitur* (Lyons, 1581) exhibits a constructive scepticism which, critical of Aristotle, emphasizes the need for experiment.
2. Isaac La Peyrère (1596–1676) and Baruch (Benedict) Spinoza (1632–1677) exemplify the application of scientific techniques to biblical study; Richard Popkin (1987) has argued that this, even more than Copernican cosmology, undermined the theological foundations of Judaism and Christianity.

Science and Religion in the Modern Period

Since the seventeenth century science has conflicted with religious tradition in three ways:

- (a) Numerous specific instances have arisen of scientific results contradicting statements made by religious authorities.

- (b) The requirement that theory be supported by reproducible experimental evidence has not only cast doubt on earlier statements on nature by religious authorities, but has shaken confidence in the traditional religious method of deriving information about the world from traditional texts.
- (c) The teleology which characterized the Aristotelian understanding of nature and conveniently supported the “argument from design” has been abandoned.

The broad result of these conflicts within Judaism has been a denominational split. The Reform branch has accepted the scientific revolution in principle; Orthodox traditionalists range from outright denial of scientific results to a variety of accommodations and reinterpretations designed to safeguard the integrity of the traditional doctrine of the divine origin of the Torah.

Descartes (1596–1650) held that all change and movement in the physical world were to be explained in purely mechanical terms; Spinoza (1634–1677) scathingly dismissed the idea of final causes in nature as a superstition, a figment of the human imagination (*Ethics*, Appendix to Part 1); and David Hume (1711–1776) reduced causation to mere “association of ideas” (*Enquiry Concerning Human Understanding*, Section III). Teleology, as a scientific hypothesis, was dead.

Organic evolution, proposed by Charles Darwin in his *Origin of Species* (1859), posed three challenges to the traditional understanding of the Biblical Creation story:

- (a) It reinforced the claim, made already before Darwin and contrary to the Bible, that there were human beings long before the 6,000 years ago that Adam and Eve were supposed to have been created.
- (b) It denied a special act of creation of humankind, asserting the continuity of life forms and the heredity of *Homo sapiens* from more primitive species of animal.
- (c) It posited a process – natural selection – by which human beings, as well as other creatures, could come to exist without having been specifically planned. No longer was it necessary to posit a Designer who had planned each detail of the design.

The last of these was at the same time the most fundamental challenge to faith and the weakest part of the theory. For Darwin had no plausible explanation of how variation occurred, or indeed of the reproductive process itself. Only a century later, once the structure and function of DNA were unraveled, was a coherent model available for a self-replicating molecule able to carry the information needed for the formation of a new individual organism; minor, accidental variations in the genetic code could account for the evolution of distinct new species. The idea of human beings or any other creatures being “designed” was finally rendered superfluous.

In the nineteenth and early twentieth centuries, some Orthodox Jewish thinkers felt they could accommodate evolution within a traditional scheme. Even before the *Origin of Species* was published, Israel Lipschutz (1782–1860) had noted the parallel between the evolution of species and Rabbi Abbahu’s (third century) statement (*Midrash Bereshit Rabba* 9:2) that “The Holy One, blessed be he, repeatedly created worlds and destroyed them until he made this one” (*D’rush Or ha-Hayyim*). Rav Kook (1865–1935) observed that Kabbalah recognizes an ongoing process of redemption, a completion of creation, analogous to evolution (*Orot ha-Qodesh*, No’s 559 and 565). J. H. Hertz (1872–1946), Chief Rabbi of the (then) British Empire, appended to his 1936 commentary on Genesis a note in which he asserts:

... there is, therefore, nothing inherently un-Jewish in the evolutionary conception of the origin and growth of forms of existence from the simple to the complex, and from the lowest to the highest. The Biblical account itself gives expression to the same general truth of gradual ascent from amorphous chaos to order ... insisting, however, that each stage is no product of chance, but is an act of Divine will, realizing the Divine purpose, and receiving the seal of the Divine approval ... (Hertz’ emphasis)

While these and others grasped the idea of evolution as progress, they failed to understand that “progress” of this kind does not require design. They addressed the minor question of how a progression of life, even one extended far beyond the few thousand years allowed by

scripture, can be reconciled with tradition, but not the major theological issue, namely, Why is God needed, not simply as the “ground of being,” but as Author and Guide of specific events?

Medieval philosophers were troubled by the theory, attributed to Aristotle, that the universe was eternal, not created. Until the latter part of the twentieth century scientific cosmology remained wedded to the assumption that the universe had no beginning or end, or at least none that could be subjected to any empirical test. By the 1960s, however, the “Big Bang” theory had become dominant. Jewish thinkers such as Aron Barth (1968), like many Christian theologians, welcomed this as confirmation of Genesis; it acknowledged a point of origin, and it was a small step to identify this “singularity” with divine creation. But alternative cosmologies are available, Genesis specifies that the *Earth* was created (with the heavens) at the beginning, and there is no evident correspondence between the 6 days of creation in Genesis and the 13.7 billion years of modern cosmology, or the 5 billion years of Earth history, with regard to either periods of time or order of events; attempts to reconcile Big Bang cosmology with Genesis 1 engender radical, often implausible, reinterpretations of the text (Aviezer 1990; Lamm 1990; Roth 1966).

Yeshayahu Leibowitz (1903–94), who from 1961 was professor of organic and biochemistry and neurophysiology at the Hebrew University, Jerusalem, was among those who have maintained that science and religion do not conflict since they occupy totally distinct domains. Judaism, according to Leibowitz, is a religious and historical phenomenon which is characterized by a recognition of the duty to serve God according to the *halakha* (law); there is no such thing as Jewish philosophy, theology, mysticism, or science, therefore, there is no problem of the relationship between religion and science (Leibowitz 1992). J. B. Soloveitchik (1903–1993) likewise attempted to bypass the conflict with science by reducing Torah to *halakha*: even the creation story is for him not cosmogony or metaphysics but *halakha* – the *halakha* that we should engage in the creative

activity of Torah. But he does acknowledge that Torah addresses itself to natural phenomena; Torah and nature do not occupy distinct domains; however, the Man of Religion, the Man of Science, and the Man of Halakha, each bring a different set of a priori concepts with which to confront the world. Each looks at the same tree, or sunset; where the Man of Religion responds with awe, and the Man of Science by measuring in accordance with his a priori laws, the Man of Halakha confronts the tree or the sunset with the laws of the Torah, and decides what blessing to pronounce, whether the time has come for evening prayer, and so on.

What these and similar thinkers have in common (and in this they differ little from their Christian counterparts) is the assumption that the potential conflict between religion and science is with regard to the existence of God and the origin of the universe; they all agree that there is no conflict between science, which is essentially descriptive, and religion insofar as it is prescriptive. As Samuelson (1994, 261) puts it, echoing Hume, “The critical point is that right moral behaviour cannot be determined from empirical nature.”

But many philosophers have claimed connections between nature and morals, and in any case Torah covers far more than moral behavior. Moreover, as we have seen, exponents of Jewish religion in earlier periods routinely made descriptive claims about the universe that were incorrect; we cannot lightly assume that these are irrelevant to the concerns of religion. The problem is highlighted when we address the interface between natural science and *halakha*. For instance, can a *halakha* be changed if it transpires that it was based on erroneous scientific understanding? A striking example of this occurs in connection with blood typing. The Talmud unequivocally states that blood is “from the mother”:

There are three partners in [the generation of] a person, the Holy One, blessed, be He, his father, and his mother. His father generates the seed of whiteness, out of which [are formed] bones, sinews, nails, the [soft matter of the] brain in his head, and the white of the eye. His mother generates the red seed, out of which [are formed] skin,

flesh and hair, blood, and the dark part of the eye. The Holy One, blessed, be He, puts in him *ruah* (wind, spirit) and *neshama* (breath, soul) and facial appearance, and the seeing of the eye, the hearing of the ear, the speech of the mouth, the movement of the legs, and discernment and understanding. When his time comes to depart from the world, the Holy One, blessed, be He, takes His portion, and leaves before his mother and father their portion. (BT *Nidda* 31a, Munich manuscript)

A Sefardi Chief Rabbi of Israel, Ben-Zion Uzziel (1880–1953), ruled on this basis that blood typing could not be used as a means of ascertaining paternity, since “any scientific examination is nullified by this trustworthy tradition of our Sages all of whose words were spoken by divine inspiration ...” (*Sha’arei Uzziel* vol.2, 40:18). Sefari Jews’ mediaeval forbears lived in the Iberian peninsula. Ashkenazi are Jews of Northern European descent. His Ashkenazi colleague, Chief Rabbi Herzog, strongly differed, and wrote to a colleague in 1954:

... How unfortunate it is that while science is progressively conquering worlds and discovering all sorts of secrets, although it too errs at times, we bury our heads in the sand like that well-known bird and look no further with regard to scientific matters that concern our Holy Torah ... (Frimer 1991, 42–44)

Since the days of Uzziel and Herzog much progress has been made in the application of *halakha* to problems raised by new medical technology; Feldman (1974), Feldman and Rosner (1984), Rosner (1986) and Rosner and Bleich (1991) have reviewed this progress, which may be followed in dedicated journals such as the Hebrew *Assia* and English *Jewish Medical Ethics* (both websites inoperative at the time of writing) published by the Dr Falk Schlesinger Institute for Medical-Halakhic Research at the Shaare Zedek Medical Center, Jerusalem (www.medethics.org.il). Progress is also summarized in professional guidelines such as the *Compendium on Medical Ethics* issued at intervals by the Federation of Jewish Philanthropies of New York.

Another area of interface between Jewish tradition and science is that of conservation and environmental protection (Solomon 1992;

Solomon 1994). The fundamental duty of caring for the environment is rooted in the goodness of the created world (Genesis 1:31), in the commandment to Adam to work on the garden of Eden and look after it (Genesis 2:15), and through rabbinic elaboration of biblical rules such as the prohibition of destroying productive trees (Deuteronomy 20:19) and the requirement to rest the land in the sabbatical year (Leviticus 25:4). It has been expressed not only by theologians, but through public statements such as the “Jewish Statement on Nature” adopted by the Board of Deputies of British Jews in 1990, and by the activities of dedicated organizations such as the Noah project; a long list of American Jewish environmental organizations is available online (<http://jrf.org/files/Jewish%20Environmental%20Organizations.pdf>).

Conclusion

To the question posed at the beginning of this essay, “Is there any *organic* connection between Jewish thought and scientific discovery?” we answer affirmatively. The Talmud itself demands, if in an ancillary role, answers to astronomical and biological questions, and does not expect to obtain those answers by poring over scriptural texts, even if allusions are sometimes sought in the precise wording of scripture. Moreover, “Jewish thought” encompasses more than the Talmud, ranging from biblical awe at God’s creation, to the philosophies of the Middle Ages, to excitement at the new philosophies and scientific conceptions at the onset of modernity, to contemporary concern about conservation of the environment, all religious concerns which generate interest in the way the natural world works.

The precise forms in which the normal human inquisitiveness of Jews has been channeled have been influenced by social and economic pressures as well as tradition, but we should not doubt that the love of learning and enquiry encouraged within Jewish tradition have stimulated scientific enquiry by Jews, and the

positive attitude of the Hebrew scriptures to the natural world has fostered a respect for nature and concern for its preservation.

Natural Selection

Saverio Forestiero

University of Rome “Tor Vergata”, Rome, Italy

The Idea of Natural Selection as a Principle for Adaptation

The theory of natural selection, developed independently by C. Darwin and A. R. Wallace, was first publically presented by a joint reading of two separate papers at the July 1, 1858, session of the *Linnean Society of London*. Soon after these two papers were printed in the 3rd volume of the *Proceedings of the Society*, which appeared August 1858 (Hodge 1992). Later the theory of evolution by natural selection was developed in two major works by Darwin: *The Origin of Species* (1st ed., 1859; 6th ed., 1872) and *The Descent of Man* (1871) and it was treated extensively by Wallace in his *Darwinism* (1889). The theory of evolution through natural selection is based on four observations that lead to one conclusion: (1) there is intraspecific variation in the majority of characters, (2) the biological (reproductive) success of an individual is linked to the suite of characters he possesses, (3) much variation is inherited by descent, and (4) since organisms of the population of a species produce more offspring than environment can sustain, competition for limited resources leads to a struggle for existence (Futuyma 1998). Therefore, the inevitable conclusion is that species evolve as a result of differential reproduction of different genotypes in a population (Endler 1992).

Some Epistemological Questions

Natural selection, or the differential reproduction of genotypes in a population, is both cause and effect (Ridley 2004). From a phenomenological point of view, natural selection is an effect: it is the result of the interaction between phenotypically expressed genetic variation and variation in ecological factors directly acting on individuals;

these environmental factors alter the probability of individual survival or fecundity (Williams 1992; Futuyma 1998; Ridley 2004). Basically, every time a population passes from one generation to the next, a spontaneous process of selection occurs. Once selection has occurred, the genotypic composition of the new population has become different from the genotypic composition of the starting population. While at a phenomenological level, natural selection can be seen as an effect, at the theoretical level, i.e., the explication of evolutionary processes, natural selection is an etiological, causal factor of evolution from one generation to the next (microevolution).

Natural Selection and Adaptation

Natural selection is a nonrandom difference in reproductive output among replicating entities, first of all individual organisms (but sometimes also ► [genes](#), and perhaps species), due to differences in survival in a specific environment (Williams 1992). Natural selection leads to an increase in the proportion of beneficial (for an individual), heritable characteristics within a population from one generation to the next. Natural selection is one of the basic mechanisms of the evolutionary change (other recognized causes of evolution of a population are genetic drift, mutation, ► [gene flow](#), and inbreeding) (Futuyma 1998; Ridley 2004), and it is the main process responsible for the production of genetic evolutionary adaptation (Williams 1966; Futuyma 1998; Ridley 2004). Tied to the idea of natural selection is the concept of fitness. The fitness of an organism (overall ability to survive and reproduce) is based on many aspects of the organism, which means that the mechanism of natural selection can act on a wide range of characters, heritable traits, from morphology to behavior (Ridley 2004). The fitness of a genotype can be measured and corresponds to the number of offspring of that type that reach adulthood. The fitness differences among individuals are differences in the propensity to survive and reproduce (Williams 1966).

Ultimately, there is evolution only through selection against variable, heritable characters linked to fitness. Without variability, selection could not occur.

Main Properties of Natural Selection

- (a) *The link with random causes.* The selection mechanism is powered by random causes. In the end, selection depends on genetic variability and the ultimate source of variation is the random mutation of genetic material (Futuyma 1998; Ridley 2004).
- (b) *Simplicity.* Through a very straightforward procedure it is considered to be possible to produce extremely complicated and complex structures and processes, provided, however, that the procedure is repeated a great many number of times, hundreds of millions of times (Futuyma 1998; Ridley 2004).
- (c) *Universality.* The procedure of natural selection is independent of the type of material support. The logic, the rules followed in implementing the procedures, does not vary with the material nature of genes or with the type of organism. The mechanism of natural selection is only one and it is valid for all organisms (Futuyma 1998; Ridley 2004).
- (d) *Automaticity.* The mechanism goes into action whenever certain conditions are in effect (Futuyma 1998; Ridley 2004). Some of these conditions relate to the population, others to the interaction between other organisms and the environment. In any case, the mechanism always rewards individuals (or genetic organizations) that exhibit the best performance under given circumstance. The process of natural selection can explain adaptation to natural conditions without having to resort to teleological explanations (Williams 1966; Futuyma 1998). To explain biological evolution it is not necessary to consider any causes outside of nature. There is no need to invoke supernatural forces because adaptive evolution is the result of an automatic selective process that operates always and continuously.
- (e) *The here and now.* Natural selection is an “opportunistic” agent in that it springs, as a process, from a spatially and temporally restricted interaction; natural selection cannot act prospectively, i.e., providing for a future environmental scene, or for any future needs of the species (Williams 1992). Every environmental action on the individual produces selective effects only applicable to the present time. In practice, the “select” and “success” can be challenged in every generation. In other words, in biological evolution there is no space for the idea of a project.
- (f) *Non-signification.* Selection is not a process designed to produce particular types of species (e.g., our species) in place of certain other species (Williams 1966). In other words, natural selection is not a mechanism subject to a project (Williams 1992; Futuyma 1998; Ridley 2004). All this is summarized in the simple, popular statement; *selection is blind to the future.*

The Effectiveness of Natural Selection

The effectiveness of the differential reproduction of genotypes as a result of Darwinian evolution has been repeatedly demonstrated by observations in nature and laboratory experiments conducted on many different types of organisms: bacteria, plants, and animals (including our species) (Futuyma 1998; Ridley 2004). The mechanism of natural selection is pervasive and it presumably has acted since the appearance of the earliest forms of living beings.

Description

Natural theology, as traditionally understood, seeks arguments for the existence of God on

grounds external to revelation; it also explores questions about the nature of God and the relationship between God and the world. In medieval Christian thought, natural theology was argued deductively in terms of ontological reasoning – either on *a priori* grounds of logic, notably by Anselm of Canterbury in the eleventh century or on *a posteriori* cosmological and teleological grounds, as in the Five Ways argument of Thomas Aquinas in the thirteenth century. Then, with the rise of modern science, natural theology tended to develop inductively during the seventeenth and eighteenth centuries in terms of “argument from design” – that is, from the evidence of the superb ordering of nature’s life-forms. The latter was comprehensively described by William Paley in his celebrated *Natural Theology: or, Evidences of the Existence and Attributes of the Deity, Collected from the Appearances of Nature* (1802).

In due course, the deductive arguments were shown by Kant and Hume to be philosophically inadequate, and Hume, in particular, provided substantial objections to the design argument, which was further weakened by the advent of Darwin’s theory of evolution (1859). Strong pressure also came from the authoritative and initially uncompromising view of the leading Protestant theologian of the early 1900s, Karl Barth, who viewed the metaphysical nature of natural theology as inimical to the theology of revelation. A further attack arose from the logical positivism (or logical empiricism) of early and mid-twentieth century philosophy with its narrow criterion of verifiability as the way to determine the validity of any truth claim. This made metaphysical ideas unfashionable, particularly those of natural theology.

However, a new-style natural theology (NNT) is emerging from the science-and-theology discourse of the past three decades. It aims to formulate a widely embracing account of our multileveled evolutionary world, on the assumption that it is the work of a beneficent creator. This project stands alongside the present-day work of philosophers of religion who seek further development of old-style natural theology, along philosophical and scientific lines. Richard Swinburne, notably, argues that the existence of God is

more probable than the nonexistence of God by estimating a probability rating for each argument and pointing to the consequent cumulative rating.

The science-and-theology discourse itself has been conducted for the most part with Christian belief in mind, but with other religions increasingly involved. To a large extent it was provoked by one of the great scientific discoveries of the twentieth century, namely, that the universe itself has a history – that of a 13.7-billion-year process of expansion and cooling, together with the formation of a vast number of solar systems, at least one of which has given rise to an astonishing variety of life.

From consideration of the expanding universe as seemingly fine-tuned for life to emerge (see ► [Anthropic Principles](#)), the discussion moved to the area of biological evolution and the biological foundation of *Homo sapiens*. It then focused on questions of human personhood and powers of cognition, especially the capacity for language, symbolic understanding, and, hence, culture. This in turn raised epistemological questions, that is, questions about the nature and process of human knowing. Alongside these topics, the question of the nature and locus of divine action in the world has been addressed in great detail.

Throughout the discourse, the interaction between science and theology has ranged widely, from the aggressive broadsides of ► [scientism](#) and ► [creationism](#), through dualistic claims of non-engaging coexistence to a quest for consonance between the two areas of inquiry. And it is in the exploring of such consonance that NNT finds space for development.

As systematic theologian John Macquarrie put it in the 1970s, NNT would maintain continuity with the old form of natural theology in that it would continue to perform the same basic function of “providing a bridge between our everyday thinking and experience and the matters about which the theologian talks: it will relate religious discourse to all the other areas of discourse” (Macquarrie 1977, p. 57).

One of its leading proponents, John Polkinghorne (1991:51), writes: “I believe that we are living at a time of revival of natural theology, more modest in its tone than its

predecessors of earlier centuries. It speaks of insight rather than demonstration. Its aim is not the classic goal of proving the existence of God. Rather, it seeks to show theism as providing a coherent and deeply intellectually satisfying understanding of the total way things are” – through integration of insights from the sciences, the arts, ethics, and Christian theology itself.

Alister McGrath (2008:19) adopts a similar integrative approach. On the basis of a Christian doctrine of creation, combined with ideas from the natural and human sciences, he develops an account of the nature and meaning of human *being* within a world created to show forth the great qualities of truth, goodness, and beauty.

Keith Ward (2003:602–5), on the other hand, places natural theology in a broad theistic setting that is not linked specifically to Christian tradition. But he, too, looks for a wide-ranging engagement with the world, describing it as the attempt to show how science, history, morality, and the arts are so related that a total integrating vision of the place of humanity in the universe may be formulated – an attempt that will be “more of an imaginative art than an inferential or deductive science”.

The term *natural theology* is sometimes linked to the term *theology of nature*, but they have different meanings. The latter refers to a more narrowly and ethically focused project concerning the significance of the world of nature, while the former ranges widely and is more philosophically oriented as it seeks to develop an integrative account of the entire sweep of reality – in other words, a ► [theological metaphysics](#). And it is usually with Christian thought in mind that such a theological metaphysics is named “natural theology.”

NNT seeks to describe, in narrative form, creation’s “struggle upwards through matter, life, thought, history and culture” (Christopher Mooney 1991:319) – aiming thereby to address questions about the origin, meaning, and purpose of it all. And if it is to do justice to the full range of human personhood within this broad context, it needs to link Christian belief about the creation not only to the natural and human sciences but also to the humanities – not only to the realm of

Natural Theology, Table 1 Place of NNT in western thought

A layout of broad areas of western thought, drawn from discussion with Niels Henrik Gregersen, John Polkinghorne and Keith Ward. The two outermost boxes represent extremes of a range of integrative approaches that includes 'theistic naturalism' and 'process theology'.

logic and reason but also to the realm of aesthetics and the imagination. Indeed, NNT may be thought of as a twofold bridging activity: internally creating a grand-narrative framework in terms of theology's reflections on the religious, scientific, aesthetic, and moral dimensions of human thought and understanding and externally linking this framework to the general discourse of academy and society.

Jürgen Moltmann (1985:58–9) refers to these two roles as an internal hermeneutical function of intellectually underpinning the Christian faith and an external educative function of relating key theological ideas to more general discourse. But he adds a third: an [eschatological](#) function of anticipating “the knowledge of God in glory” – in other words, providing metaphorical insight into the nature of this world as “parable of the world to come.” The eschatological dimension is a fundamental aspect of Trinitarian theology, even if discounted by those who hold to a more philosophically based theism. It provides NNT with the key metaphysical idea, clearly

speculative but profoundly explanatory, that this amazing, beloved, costly, and deeply interrelated world constitutes the raw material for a new creation yet to be realized.

The table below shows a way of representing the place of NNT in western thought (Table 1). Whereas systematic theology strives for coherence within the broad scope of theology itself, NNT aims, in this scheme, not only to provide an internally unifying perspective but also to extend that coherence externally, through the engagement between theology and the intellectual world at large. The connecting lines and arrows show something of the overlap and interplay among these areas of thought.

The interdisciplinary nature of natural theology has raised questions about its identity vis-à-vis the fields of science and theology. Its relationship with each has often been uneasy. So, too, has been its relationship with philosophy. It deals with meta-physical questions (see the beginning of section “[Conceptualization](#)” below) and makes use of philosophical language and concepts – but it does

so within a theological framework and thus stands in contrast to the more empirical, naturalistic perspective of much western philosophy. And for the theologian, it is the metaphysical aspect that may seem to intrude into the narrative basis of the Christian faith. Indeed, many contemporary theologians treat the prospect of a metaphysical dimension to theological thought with considerable reserve, or even suspicion.

Any such metaphysical scheme needs to develop from some organizing idea or theme about the nature and purpose of God as creator. The point of departure may be either the experientially based, richly detailed theism of one of the monotheistic religions on the one hand, or a more restricted and abstract theism characteristic of philosophy on the other – and it is philosophical theism, in its various forms, that is commonly adopted within science-and-theology. However, many find greater explanatory power in well-winnowed Christian thought, especially ► [Christianology](#), when dealing with questions about horrendous suffering and ultimate meaning.

Working from the latter perspective, NNT is in the process of establishing itself. Its concern is to form a theological grand narrative that harmonizes the generalities of science with the particularities of Christian tradition. In terms of the final burst of Dietrich Bonhoeffer's theological thinking (in 1944), the challenge is then to express the key concepts of the Christian gospel (creation, fall, atonement, repentance, faith, the new life, the last things) within such an NNT synthesis, using fresh metaphysics and expressing it all in the language and ideas of the modern world (Bethge 1975:150). And in the present global context, there exists a further challenge: to remain open to religious insight in all its variety, and thereby open to continual testing and reinterpretation of the narrative.

As an organizing idea, NNT could choose, for example, George Ellis's (1994:1–14) axiomatic statement that, operating within the grain of the divinely instituted laws of nature, “God so creates and sustains the universe as to make possible high-level loving and sacrificial action by freely acting self-conscious individuals” – an idea that would immediately place stringent requirements

on the whole unimaginably complex and costly creation process.

But however it is structured, NNT is faced with the creative task of drawing together insights from all four areas of reflective theological analysis listed in the table below. The interplay between theology and science over recent decades has been lively and remains important. But input from the other three areas of engagement would surely make for a well-grounded natural theology – a theological worldview to set against the varieties of fundamentalist thought, secular and religious, and to leaven discussion with the world at large, whether dealing with key issues in public life or the big questions of human existence.

Self-identification

Science

NNT does not identify itself as a science in the sense of theory-based empirical inquiry about the world. Instead, it embraces the findings and insights of the sciences and humanities in order to place them in an integrative theological framework of understanding.

Religion

This theological framework acts as a meeting ground for science-religion discussion. As such, it is not a religion but aims to help those with theistic (usually Christian) belief develop self-understanding and intellectual confidence for their role in a multicultural, multifaith world.

Characteristics

NNT acts as a bridge between theology and key insights of the sciences and humanities. It does so by virtue of its integrating role of placing the meta-questions about human existence and destiny within a metaphysical framework. In this way, it plays a sense-making role that depends strongly on the organizing (foundational) idea from which it operates. An example of such an idea is given in the second last paragraph of

section “**Description**”. A more theologically based statement would perhaps refer to questions of divine-human relationship and its ultimate purpose. In either case, it is this general bridging-integrative concern that is the distinctive feature of NNT. Its justification will lie in the extent to which it provides an intelligible and persuasive account of reality in its variety of aspects.

Relevance to Science and Religion

NNT is concerned with the entire sweep of science-and-religion discourse, offering criteria of assessment, both theological and philosophical, and opening up space for the use of metaphysical ideas in the discourse, especially (a) the notion of other levels of reality than the merely physical and (b) concepts such as ► **spirit**, ► **economy**, and sociality that may be invoked as key aspects of the created order.

The relevance of the new natural theology as part of science-and-religion:

- (a) *In teaching*: NNT can help teachers of religion/theology take into account the scientific world picture, thus offering a richer understanding of the nature, meaning, purpose, and destiny of this evolving world. And, in emphasizing the epistemic limits of scientific inquiry, NNT can suggest to scientists a wider framework of understanding for their world-picture. In both ways, it can be used to counter the fundamentalist claims of scientism and creationism.
- (b) *In careers*: NNT is an open-ended, world-affirming enterprise that encourages engagement across social and intellectual boundaries. It may therefore be significant for politicians involved in clashes of cultures and religions and for the clergy of major faith traditions in the task of preparing their laity for the challenges of multicultural society.
- (c) *In an academic setting*: By virtue of its interdisciplinary nature, NNT can raise awareness of epistemological criteria and the discipline-specific nature of rationality. As a metaphysically based, scientifically

aware theologically serious academic endeavor, NNT is well placed to promote interdisciplinary engagement and to highlight the crucial multi-perspective nature of the quest for truth. Here it stands in a mutually critical relationship with the liberal, empirical, naturalistic thinking that is common in much tertiary-level thinking.

- (d) *In society*: In its bridging role, NNT can assist theology in its participation in many of society’s debates about politics, law, economics, the media, education, medicine, and family life. “Where is high-quality, theologically informed attention being paid to such matters?” asks David Ford (1999:18), adding that such debate requires collaboration across disciplines, faith, communities, and nations. NNT seems well placed to participate in such discussion.

Sources of Authority

Macquarrie, J. (1977). *Principles of Christian theology*. London: SCM.

A much-used text that discusses the makeup of a new-style natural theology.

Polkinghorne, J. (2008). *Theology in the context of science*. London: SPCK.

Polkinghorne, J. (2000). *Faith, science & understanding*. London: SPCK.

Polkinghorne, J. (1998). *Belief in God in an age of science*. Newhaven: Yale University Press.

The first of these three shows the need for a science-style, bottom-up approach in framing theological discourse. The next brings scientific and theological expertise to the reappraisal of several key topics. The third advocates the broadening of natural theology to include the arts and treats epistemic issues in detail.

McGrath, A. (2008). *The open secret: A new vision for natural theology*. Oxford: Blackwell.

McGrath, A. (2009). *A fine-tuned universe: The quest for God in science and theology*. Louisville: Westminster John Knox Press.

Together with a comprehensive framework for a new Christian natural theology, drawing upon

Augustinian tradition (re the Fall etc.) and offering the vision of a world created to show forth the great qualities of truth, goodness, and beauty.

Root, H. (1962). *Beginning all over again*. In *Soundings*. Cambridge: Cambridge University Press.

A compelling argument for a natural theology that will help theologians to engage the mind and imagination of the poet or novelist or dramatist or film producer.

Monti, A. (2003). *A natural theology of the arts*. Aldershot: Ashgate.

A well-structured development of the notion that it is the “real presence” of God that underlies great works of art, using ideas from science and theology

Ward, K. (1982). *Rational theology & the creativity of god*. Oxford: Blackwell.

Ward, K. (2008). *The big questions in science & religion*. West Conshohocken: Templeton Foundation Press.

Ward, K. (2003). Natural theology. In *Encyclopedia of science & religion*. New York: Macmillan.

A combination of theological and scientific ideas marked by philosophical precision and expertise in comparative theology.

Ellis, G. (1993). *Before the beginning*. London: Bowerdean/Boyers.

A cosmologist's account of the universe as designed to give expression to the good.

Swinburne, R. (2004). *The existence of God* (2nd ed.). New York: Oxford University Press and a simplified version, (1996). *Is there a god?*. Oxford/New York: Oxford University Press.

A key contemporary philosophy-based account using logic and science to argue the likelihood that a god exists – one who would desire the existence of humankind and, controversially, even the costly soul making involved.

MacDonald, S. (1998). Natural theology. In *The Routledge encyclopedia of philosophy*. London: Routledge.

A lucid entry, centered on philosophical assessment and categorization.

Craig, W. L., & Moreland, J. P. (Eds.) (2009). *The Blackwell companion to natural theology*. Oxford: Blackwell.

In-depth arguments for the existence of God by a team of Christian philosophers, written largely from a theologically conservative perspective.

Ethical Principles

Commitment to the search for truth, however manifested; open-mindedness vis-à-vis the search for understanding in and through other faiths and traditions; humility about the nature and scope of human knowledge; and an inclusive approach in the task of formulating a grand narrative of the world's unfolding.

Key Values

Truth, goodness, and beauty, as manifested in (a) the creation, (b) human living and creativity, and (c) the work of NNT itself. The quality of *to kalon* (the good/beautiful/just right) (Kittel and Friedrich 1985:402–5) is a mark of fruitful theories in physics; it should surely be reflected in all disciplines, including NNT.

Conceptualization

Conceptualizing such terms involves a largely metaphysical mode of thought, that is, it is concerned primarily with matters of ontology, but also with epistemology and axiology – that is, with the multi-leveled nature of reality, with the nature and manner of human knowing, and with ultimate questions about values and meaning. NNT seeks to address concepts such as those listed above (in section “[Key Values](#)”) through the construction of an ordered and consistent picture of the world as a metaphysical framework of understanding concerning God, humanity, and the cosmos in relation to one another.

Nature/World

Within such a framework, NNT would locate nature (the physical universe) at the first level in a series of levels of reality (see section “[Reality](#)” below). Considering nature as a whole, we may note that human beings have emerged as part of a vast, multi-faceted evolutionary process that operates on cosmic, terrestrial, and biological scales. This evolutionary history has been punctuated by moments of emergent novelty, notably the transition from inanimate to animate entities and the first appearance of consciousness. These key stages were followed by the development of self-consciousness and, in due course, the entire range of human cognitive faculties. Altogether it is a process marked by a fine balance of contingency and necessity and seems superbly designed for life of great complexity. From a theological point of view, the underlying rationality of nature may be seen as a reflection of the rationality of its creator, and its meaning and purpose can be summed up in the phrase “world in the making,” the raw material for a new creation yet to be realized.

Human Being

NNT places the concept of human personhood within the widest possible context, seeing it as central in the forming of a credible account of reality – and as the main subject matter held in common by theology and science. NNT acknowledges and affirms the emergence of *Homo sapiens* within the processes of biological evolution while standing against the reductive idea of a human being as no more than a physical mechanism. Indeed, from this biological foundation, there has developed a human brain/mind complex of remarkable capacity for self-consciousness and a range of other cognitive faculties, including the ability to think abstractly and to project its thinking far into the future and into the past. These have led to the emergence of human culture in all its richness – the feature that most distinguishes human beings from the other hominids. The social context enables individual members to flourish through language and art, enhanced by the transmissible nature of culture

from generation to generation. On the theological side, NNT must take account of the higher elements of human personhood associated with the capacity to love sacrificially, respond to moral challenges, perceive meaning and beauty, and to believe and hope in God.

Life and Death

Again, NNT places life/death within the context of the entire evolutionary process, which cannot run its course without natural selection which, in turn, cannot take effect without limitation of life-span. In the case of human life and death, theologians who affirm NNT would reject the contrasting reason for death espoused in the Augustinian tradition of Christian thought, namely, that death is the consequence of a primordial sinful act. The creation theology associated with St. Irenaeus (who lived about two centuries before St. Augustine) is more in tune with the scientific picture and, in this respect, more congenial to NNT. It suggests that human nature, marked as it is by a sense of finitude and alienation, is simply at the early stage of a path toward fullness of being-in-relationship. And insofar as NNT develops within Trinitarian theology, it would look expectantly to an eschatological future that develops from the divine act of resurrection – that is, from the transformation of the entire creation.

Reality

Science and theology are often seen as complementary ways of seeking understanding of the world, involving mental models of reality. These disciplines are engaged in inferring reality from the way their models and theories make sense of great swathes of physical data on the one hand and great swathes of spiritual experience on the other – and, indeed, from the explanatory power displayed by such models and theories. And the very power of the human mind to think abstractly, in terms of models and theories, constitutes part of reality. This facility enables the mind to explore the notion of a hierarchy of levels of existence. George Ellis (2002:1–27) postulates the following set of

levels: (a) the physical world of energy and matter; (b) the contents of human minds; (c) the set of *possible* physical and biological forms (our world being a subset); (d) a platonic realm of abstract realities such as mathematical forms, physical laws, powerful symbols, etc.; (e) the set of values, meanings, and purposes underlying the created order; and (f) the fundamental metalevel of the being of God. These may all be considered to be aspects of reality insofar as they take effect in the realm of the physical.

Knowledge

It is widely held that there is a critical-realist relationship between the knower and that which is known – that the known is real, but the knowledge of it is less than perfect because of the finitude and limited perspective of the knower. Intellectual knowledge is acquired through a range of rational modes of knowing, varying from the mathematical in physics to the metaphorical in the humanities. The way of knowing depends on the nature of the subject matter, and all modes of knowing involve, in varying degrees, the interplay of perception, reason, emotion, intuition, and imagination. These cognitive faculties are engaged in the search to know the way things are, thereby contributing to a coherent understanding of the world. Such inquiry, with its formulation of models and theories, invariably requires acts of personal assessment, subject to aesthetic criteria such as simplicity, coherence, and explanatory power. This personal aspect, according to Michael Polanyi, involves the use of “tacit knowledge,” that is, background knowledge that resides in any scientific, cultural, or religious tradition and is learned through apprenticeship in the tradition (Monti 2003:17–22). It is knowledge that cannot be altogether explicitly expressed (“we know more than we can tell”) but is nonetheless relied upon in the exercise of the imagination as it focuses on and apprehends the sometimes surprising disclosure and intrinsic claim of the subject matter.

Truth

There are different kinds of truth – for example, the truth of a mathematical statement, the truth of

a news item, and the (existential) truth of a person’s commitment to a task or cause. These are different kinds, but they all reveal something of the way things really are. Hence the Greek word for truth, *aletheia*, which refers to that which is unveiled. It is widely accepted that the search for truth is what intellectual inquiry is about, despite postmodern skepticism about the validity of the very concept of truth. And it is generally understood that human knowledge is not absolute but rather, in varying degrees, provisional, approximate, corrigible, and incomplete. Nevertheless, scientists do lay claim to increasing verisimilitude (similarity to what is actually the case) between their theoretical models and the reality they describe, as is well exemplified in the growing understanding of the physical nature of light over the past three centuries. Theologians, too, see a progressive accumulation of insight into the nature and character of God as shown in the biblical account of the history of Israel – a development which, from the point of view of the Christian church, continues through the New Testament writings and far beyond. Both science and theology are concerned with epistemic integrity. This implies the need for rigorous assessment of their truth claims – in terms of internal coherence of a scientific theory or a theological doctrine and, especially in the case of theology, external coherence vis-à-vis knowledge from other disciplines.

Perception

Central to the development of human cognition is the determination to see and interpret patterns within the data received. The ever-present search to know and understand involves perceiving a pattern – and the human brain is superbly made for this task, whether in everyday quests for explanation or in response to the larger existential questions. It is a task that involves perception in collaboration with the exercise of reason, emotion, intuition, and creative imagination. The task of developing natural theology itself is a matter of perception in the first place – of beginning to see the possibilities of a reinvigorated NNT. Alister McGrath (2008:3)

describes the task as one of discernment, of viewing the world through the spectacles provided by Christian theology as a whole – to which we may add John V. Taylor's (1972:19) remark that the spirit of God enables us "not by making us supernaturally strong but by opening our eyes." Then, as the late English poet Kathleen Raine put it, we may see the beauty that is "the real aspect of things when seen aright (in the right way) and with the eyes of love" (Mayne 1995:139).

Time

The relationship between God and time is highly relevant to NNT and the science-and-religion discussion. It is conceived in two contrasting ways, as pictured from a God's-eye viewpoint. On the one hand, God is said to be outside time and therefore to hold an atemporal view of the creation, seeing it as a "block universe" in which all cosmic history is present to God "at once." On the other hand, from what is perhaps a more common NNT viewpoint, God is said to be all the greater if the being of God is characterized by *both* eternity and temporality – eternal with respect to consistency of character but temporal in experiencing the creation as it actually is in its openness to the future. Furthermore, if the natural world is a system of systems that is inherently indeterminate (not rigidly clockwork-like) in its unfolding – an admittedly contested idea concerning the exactness of description of material systems in terms of the equations of chaos theory – its future is genuinely open, that is, not calculable, even in principle, even by God. This would then open the way unambiguously to the costly gift of human free will from a graciously self-limiting creator.

Consciousness

This is the inward aspect of mind/brain operation, perhaps the most important development in cosmic history as the universe began to produce minds that could think about it. How the subjectively felt inward dimension of thinking relates to the objectively researched, outward dimension of neural process is, and will probably continue to be, largely unknown territory. The emergence of

Homo sapiens at least 160,000 years ago was marked by a substantial increase in powers of cognition, including self-awareness. Paleoanthropologist Stephen Mithen (1996) offers a tentative but compelling account of the prehistory of cognition in which the hominid brain/mind advances from a configuration of three separate modal intelligences (concerned respectively with social, technical, and natural-world intelligence) to a state of full "cognitive fluidity." This phrase implies not merely greater complexity but also flexibility and dynamic interaction between the different parts of the brain, making for greatly enhanced cognitive ability. With this finesse came high levels of creativity in toolmaking, social organization, and symbolic representation, leading ultimately to culture in all its richness.

Rationality/Reason

These are related concepts, but rationality is more than reason. First, that which constitutes the rationality of a particular body or item of thought does not reside simply in its logic structure, but in the pattern and meaning perceived through the interplay of reason, emotion, and intuition under the umbrella of creative imagination (as mentioned above in the subsection on "[Knowledge](#)"). Second, rationality in each discipline is constrained internally by the nature of the subject matter itself and externally by the need for coherence with the insights and knowledge of other disciplines. Third, it is a mistake to see faith and reason as antithetical. Faith merits the claim to be rational insofar as it is the response to an accumulation of well-tried interpretation of evidence – and, as such, it is the ground on which much of the enterprise of theology is built, as it pursues a dialogue between evidence and interpretation.

Mystery

This is related to the finitude and limited perspective of human thought. Human knowledge is partial and incomplete, leading us to speak of that which transcends it as "mystery." In everyday use, the term implies something hidden or

secret or, perhaps, yet to be revealed. At a deeper level, there exists the sense of wonder and mystery at the limits of our knowledge of the natural world. As physicist Victor Weisskopf (1979) remarked, “Our knowledge is an island in the infinite ocean of the unknown” – the unknown that includes the mystery of the meaning and destiny of the universe, given the prospect of its eventual heat death. But it is in theology that the concept of mystery is at its deepest level, especially in Christology with its attempt to understand the divine/human nature of Christ. In a letter to fellow pastors, Dietrich Bonhoeffer referred to this “holy mystery which is a concept that theology has the duty to guard.” He goes on to warn of the mistake of thinking that it is “the task of theology to unravel God’s mystery, to bring it down to the flat, ordinary human wisdom of experience and reason. It is the task of theology to preserve God’s wonder as wonder, to understand, to defend, to glorify God’s mystery as mystery.”

Relevant Themes

The significant contributions that NNT can make to the science-and-religion discourse may be summarized as follows: (a) affirming the widely ecumenical spirit of the discourse, (b) being open to new ideas and concern for philosophical precision, and (c) complementing these qualities with the theological insight of a well-winnowed religious tradition. If full weight is given to the latter, it can surely enrich science and religion in tertiary-level settings and contribute to serious study and debate in society at large, especially with respect to religious education in schools, interfaith engagement, and the issue of global warming. Alongside these contributions, there exists the task for which NNT is especially fitted: the forming of a non-totalizing vision of the world that enhances hope for the future, celebrates society in all its diversity and particularity, and offers a convincing theodicy, however limited, in the face of acute suffering and unjustness.

Description

The notion of naturalism extends through multifarious fields of research and has given rise to a very broad, and emotionally loaded, debate over the last two decades. Contrary to most other philosophical notions, this particular notion is not only of concern to philosophers but is widely discussed and analyzed in almost every academic discipline. In recent years recent years, it has even reached outside the defined borders of the university and has provoked an intense debate in the general public. This debate is not limited to the philosophical definition of the notion but is teeming with personal, educational, and religious implications. One reason for the broad, and often vague, use of the notion of naturalism could be that even within the strict borders of academic philosophy, the notion has not enjoyed any unanimously accepted definition, nor is it particularly clear what being a naturalist actually means. This entry will deal with two general types of naturalism that go under the names ontological naturalism and methodological naturalism. There are other types and subtypes of naturalism (religious, scientific, epistemological, causal, etc.), but ontological and methodological naturalisms are, without doubt, the types of naturalism most debated in contemporary philosophy and, furthermore, those with most significant implications for the relation between science and religion. Despite the complex and vague nature of the notion of naturalism, it is nevertheless possible to begin with a minimal outline of what is

generally accepted as the basic premise that all who call themselves naturalists must subscribe to.

Traditionally, since the scientific revolution in the sixteenth century, naturalism characterizes a variety of philosophical positions that notwithstanding their many differences, all have one thing in common, namely, the exclusion of any form of supernatural entities or agents in the explanation of the spatiotemporal world. Contrary to earlier forms of naturalism, which were quite broad when it came to what was included as natural, contemporary naturalism has become more restrictive, although perhaps not more clear, about what counts as a natural process or entity and thus what can be readily dismissed as supernatural. The default position of any contemporary naturalist explanation is that everything (e.g., the universe, organic life, and human nature) can be satisfactorily explained exclusively in terms of processes and entities amenable to the methods and laws established by the natural sciences. If a given problem cannot be explained within this framework, only two answers remain viable: either the natural sciences will be able to explain the problem in the future (when the theoretical and technological development reaches a higher degree of maturity), or the problem simply falls outside the naturalistic framework and can thus be explained away as an inefficacious epiphenomenon or a subjective illusion. In order to understand the self-confidence of contemporary naturalism and the philosophical problems that the vagueness of its actual content and scope entails, a very short survey of the history of the notion over the last 50 years may be in place.

The question about human nature has always been in the foreground of discussions about naturalism. For millennia, philosophy (and until the nineteenth century, theology as well) has enjoyed a prerogative when it came to explaining and understanding human nature. This situation changed drastically in the second half of the twentieth century. The birth of ► [cognitive science](#) in the 1950s and the discovery of the structure of DNA in the same years elicited a strong faith in the ability of the natural sciences to unravel the cognitive capacities of the human mind. Both scientists and philosophers began to question the alleged superiority of

philosophy with regard to understanding human nature. If human ► [cognition](#) and behavior could be explained by certain genetic structures and the biological constitution of the brain, why then should the complexity of human nature be out of reach for the natural sciences? However, the most damaging attack on the legitimacy of an independent philosophical method came from inside philosophy itself in the form of the work of the American philosopher Willard van Orman Quine (1908–2000). Quine's critique of the analytic/synthetic distinction and traditional a priori truths together with his naturalization of epistemology severely undermined the idea of the superiority of philosophical analysis and strongly emphasized the continuity between philosophy and the empirical sciences (van Orman Quine 1951).

Since the 1950s, the natural sciences have continued to gain ground in the discussion of human nature, both in academic circles and in the larger public, and, since the 1980s, particularly ► [neuroscience](#) and ► [evolutionary psychology](#) have proposed new, scientifically based syntheses that seek to explain everything human, from cognition and social interaction to ethical norms and aesthetic values. This rapid development has had important bearings on the philosophical conception of naturalism. Today, many philosophers would claim that they are naturalists. However, the meaning of the notion naturalism has changed drastically. Whereas, in the first half of the twentieth century, naturalism referred to an inquiry that respected the nature of the physical world *and* the complexity of human nature (human reason, feeling, action, and existence), naturalism today is often understood as a position that seeks to explain human nature, and everything else, by means of the methods of the natural sciences or at least by types of investigations modeled on the kind of experimental research done in the natural sciences. This development and use of the notion of naturalism have produced an intense debate among philosophers about the scientific validity of the notion. The rest of this entry will present two generally accepted philosophical attempts to define the notion, namely, as (1) ontological naturalism and (2) methodological naturalism, and will indicate some of the problems involved in each of these

definitions. By way of conclusion, the entry will briefly consider some of the implications which the philosophical struggle with ontological and methodological naturalism has for the relation between science and religion.

Ontological Naturalism

This type of naturalism (also named metaphysical naturalism) postulates that the only genuine entities and processes in the world are those whose existence can be accounted for by acceptable scientific explanations. Nature is what we assess by means of scientific investigation, and natural things are those which can be explained by the natural sciences. For an investigation to qualify as scientific, it must respect, and produce its explanations in accordance with, the basic assumptions of ► [physics](#) and ► [biology](#). The natural world is basically physical and is governed by physical laws. Natural life is constituted of elements explained by physics and organized in accordance with the principles uncovered by biology. Although it is not generally required that biological mechanisms should be explained with direct reference to physical elements, particles, or waves, physics is still considered to express the ultimate structure of reality and is taken as the model according to which the other sciences, including biology, should be conceived and developed. The ontological primacy of physical entities (no matter what is or will be considered to be the ultimate constituent/factor of such entities) is the cornerstone of ontological naturalism.

Defined in this way, ontological naturalism comes close to, and is sometimes indistinct from, philosophical notions (or positions) such as ► [materialism](#) and ► [physicalism](#). But whereas all three conjoin in rejecting supernatural entities, there are important differences to be noticed among them. Materialism (Churchland 1984), which is the oldest of the three, asserts that everything which exists is material. This position, however, ran into serious difficulties with the explanatory success of modern physics in the beginning of the twentieth century. Contrary to Newtonian physics, modern ► [quantum](#)

mechanics argues that subatomic physical particles work in ways that do not admit of any previously conceived determination of their physical effect on a macrophysical level (cause and effect in the world as it appears to the unaided eye of the observer). Quantum mechanics introduces a principle of uncertainty in our understanding of the physical constitution of the world. It is therefore incorrect, according to some contemporary interpretations of quantum mechanics, to refer to the ultimate constituents of reality by material and spatial determinations in connection to what we experience in the spatiotemporal world. There exist several interpretations of quantum mechanics that vary drastically with respect to how quantum mechanics complicates traditional physical conceptions of ► **space**, ► **matter**, and ► **time**. But it is safe to say that most interpretations stress the undetermined nature of physical systems, that is, there is more to the physical universe than uncovered by traditional macrophysics. This element of uncertainty has induced many philosophers to adopt a position more in trend with modern physics, namely, physicalism. Physicalism (Melnyk 2003) posits that everything that exists is physical despite disagreement as to what ultimately constitutes physics. Physicalism is not identical with ontological naturalism, because whereas every physicalist must be committed to ontological naturalism, not all ontological naturalists are necessarily physicalists. An ontological naturalist may accept that the ultimate structure of reality is indeed physical without agreeing that physics is the only viable disclosure of reality. An ontological naturalist may hold a pluralist conception of science in which biological or chemical explanations of, for example, the circulatory system or sulfur are not reducible to physical explanations. Thus, materialism and physicalism are restrictive versions of the more general view of the nature of reality defined by ontological naturalism.

What is, then, the actual content of ontological naturalism? The concept does not imply much about the nature that it advocates and does so merely through the very general characterization mentioned above: only entities that can be

explained by acceptable scientific explanations exist. Although, contrary to physicalism, naturalism makes room for a pluralist conception of scientific explanation, it remains firm on the claim that only entities that can be empirically verified are considered to possess reality. Everything that lies beyond empirical assessment is not granted existence, or at least, the existence of such impalpable phenomena remains suspiciously problematic in the eyes of the ontological naturalist. The emphasis on empirical assessment hinges on the circumstance that all variations of ontological naturalism subscribe to the so-called doctrine of causal closure. This doctrine states that all physical effects can be accounted for and, in principle, explained by basic physical causes. Since apparently nonphysical entities (e.g., mental states, colors, aesthetic, and moral values) bring about a de facto physical change in the world (e.g., a person behaves in a specific way because of some moral values and not others), these entities must, in some way or another, be explained by physical causes. Hence, any mental, moral, or biological causes must themselves be physical. The causal closure doctrine does not admit of *sui generis*, spontaneous nonphysical causes in an entirely physical universe. Although the causal closure doctrine may seem a very strong and apparently clear definition of ontological naturalism, it is not immune to objections. On the contrary, several problems arise when ontological naturalism is defined in this way. What counts as physical and what not? How do we explain, in terms of basic physical causes, apparently nonphysical entities such as mental states and aesthetic values that actually bring about a physical effect in the world? Furthermore, it is problematic that the lack of substantive positive content is often overshadowed by the emphatic negative characteristic that it shares with both materialism and physicalism: the rejection of all versions, kinds, and shapes of supernaturalism. Supernatural entities are here understood as those which cannot be explained by means of acceptable scientific methods of verification. Since these entities cannot be assessed scientifically, they are not an acceptable part of what

ontological naturalism understands as nature, that is, they cannot be recognized as existing and are thus defined as supernatural (beyond, or above, nature). This leaves us with a definition of ontological naturalism that says, positively, very little about the content and scope of the notion, but has a very strong profile of what it is not. Obviously, such generic arguments for ontological naturalism have met with much criticism. This section will close with two considerable problems that are often brought up in this criticism.

The Nature of Supernatural Entities

As we have seen, much of what defines ontological naturalism is the emphatic rejection of supernaturalism. An ontological naturalist does not allow for the presence or influence of supernatural entities, phenomena, or forces in her or his conception of nature and of what is considered natural. But in this way, the definition of ontological naturalism depends on the definition of supernaturalism, and this might not be as simple as it appears to be at first glance. In philosophy, supernaturalism is often immediately identified with theism and Cartesian dualism. Both doctrines assert the existence of something outside the realm of material nature, that is, immaterial entities that somehow interact with the material world. It is, however, of no avail simply to identify supernatural entities with immaterial entities, since there are plenty of immaterial entities that are readily accepted in a naturalistic conception of nature, such as numbers, concepts, values, ideas, forces, and energy waves. On the other hand, if supernaturalism is only conceived as talk about gods, souls, angels, and miracles, the notion does not yield much help in defining the content of ontological naturalism, since most philosophers have already abandoned such entities and phenomena more than a century ago. Therefore, the use of supernaturalism as the counterpart to ontological naturalism does not elucidate or explain the content of the notion itself. On the contrary, the difficulty of explaining what supernaturalism actually amounts to points to another problem in the current definition of ontological naturalism, namely, the explanation of human experience.

Human Experience and Reductionism

Another difficult problem that haunts ontological naturalism is the nature of the human [► mind](#). Somehow, human consciousness has to fit into the picture of the natural world disclosed and explained by means of the natural sciences alone. This is not an easy thing to do. How do we account for impalpable mental phenomena, such as numbers, concepts, voluntary action, color perception, or values, on empirically experimental terms? An idea of a nice meal cannot be registered, or the intensity of a moral value measured, by any generally accepted scientific standards available today. Many naturalistic attempts to circumvent the problematic existence of such phenomena have been produced throughout the years (behaviorism, epiphenomenalism, emergentism, eliminative materialism, etc.), and new proposals continue to surface. One feature, however, characterizes most of them (with the exception of emergentism): they take a reductive stance toward mental phenomena (de Caro & Macarthur 2004). Mental phenomena do not exist, or at least, they do not possess the same kind of reality as physical phenomena and entities such as a tree or a mailbox. Physical entities have an ontological priority over mental states in the sense that the former can be assessed and explained scientifically while the understanding of the latter rests on subjective and introspective accounts. Thus, depending on the degree of reductionism, mental states are considered as an illusory subjective fiction, as insignificant by-products of physical mechanisms, or as a second-degree reality with some, although inessential, bearing on the first-degree physical reality. In order to explain the experiential reality of mental states, these states are reduced to the biological substrate that underlies and sustains the manifestation of human experience. Our [► mental states](#) are not as real and efficient as they seem, but are the product of the autonomous biological functions of our highly complex brain. The rapid development of neuroscience during the last two decades has fueled the self-confidence of such reductive approaches. According to some neuroscientists (Gazzaniga 2008), neuroscience will soon be able to show how the biological mechanism of the brain

controls our thoughts and behavior, and the myth of the subjective nature of human action and mind will finally be proven false. The problem about this thesis is, however, that no reductive account has ever come even close to explaining why or how mental states seem to play such an important role in human life and behavior, not to speak of justifying the claim that this role is an illusion. The assumption that mental states possess a lower degree of reality, or in even stronger terms, that they are a subjective illusion, results in a picture of the natural world that is so far from what we know about the world in which we live and act that it can hardly qualify as a legitimate scientific approach. Humans experience color and dream about golden mountains; they think about justice and the taste of butter on warm bread, and their actions are performed in accordance with impalpable values such as good and evil. Thus, as long as ontological naturalism cannot explain why or how this is actually the case, or better, how or why this should be considered an illusion, it is not, according to the critics, a valid argument simply to assert that such things do not exist.

Methodological Naturalism

This type of naturalism concerns the nature of philosophical practice rather than the ontological status of reality. In order to obtain scientific status, philosophical practice must respect and conform to the methodological standards of empirical scientific research. This naturalistic approach does not entail metaphysical or ontological claims about the nature of reality. Such questions are considered irrelevant to, and out of reach of, any specific scientific investigation. Science is normally characterized by local and well-documented areas of research, and therefore, science does not concern itself with general and abstruse questions such as the nature of values, the meaning of life, free will, or the efficacious status of mental states. Although scientific methods may be variegated, they are all committed to some basic assumptions. Among such are empirical assessment, observation, objective measurement and verification, independence of the subject and its values (here

it must be noted that most interpretations of quantum mechanics deny any such independence), explainable results, and stable environmental factors. Now, methodological naturalists view philosophy and science as pursuing the same aims and as engaged in cognate enterprises by means of the same methods. Even though some methodological naturalists allow for slight differences between science and philosophy, the main idea is that philosophy cannot diverge from scientific methodology without compromising its own credibility. Philosophy must be continuous with the empirical sciences in order to produce a legitimate contribution to the scientific understanding of reality. Otherwise, it remains an outdated curiosity with no relation to a contemporary worldview. One way to secure the scientific validity of philosophy is to naturalize epistemology. As mentioned above, the philosopher W. O. Quine made perhaps the most important contribution to this debate in the mid-twentieth century. He argued for the rejection of analytical truth, that is, propositions with self-evident and a priori meaning that does not require empirical verification, such as "all bachelors are unmarried" or "triangles have three sides." Using elaborate conceptual analyses, Quine argued that there is no such thing as analytical propositions. Every propositional truth must eventually be demonstrated empirically, that is, every claim or hypothesis must be verified by means of the empirical sciences. On this view, "old-fashioned" philosophical analysis, such as conceptual analysis and logical deduction, is not sufficient for establishing valid claims and arguments. Philosophy needs to accept, and to model its analyses upon, a scientific methodology with regard to every kind of inquiry, be that questions about the world, human knowledge, or ethical norms. The naturalized epistemology proposed by methodological naturalism entails a serious repositioning of philosophy and philosophical analysis. Traditional philosophers such as Plato, Aristotle, Spinoza, or Kant are considered of little value to contemporary scientific debate, since their methods and arguments rest on an outdated metaphysical vision of the world. Furthermore, contemporary philosophy is reduced to a mere tool for the clarification of concepts and arguments.

Positive claims about the nature of the human mind or the constitution of nature have to find their verification in the empirical sciences and not by means of philosophical analysis. Thus, the basic claim of methodological naturalism is that philosophical methods must be continuous, perhaps even identical, with the methods of the empirical sciences. This definition of philosophical practice has, of course, been heavily criticized by various philosophers. One of the most influential contemporary arguments in this criticism is the one directed against the idea of science as a unified and internally coherent whole (Dupré 2001).

The Unity of Science

The argument for methodological naturalism hinges on the idea of a general scientific methodology common to all the natural sciences. For a belief to be warranted, it must be verified by means of such a methodology. But is it possible to speak about one generally accepted scientific methodology? Can the multitude of different natural sciences be subsumed under one generally unified methodological approach? The critics of methodological naturalism believe not, and they claim that this unity of science is an unsubstantiated myth. In order to establish such a methodology, the empirical sciences must form an internally coherent whole with no essential tension or mutual contradiction. Such a unity of science seems to imply an ultimate point of reference for all empirical sciences, which is commonly found in physics. No scientific hypothesis must be in contradiction with currently accepted physical laws and mechanisms. This, however, is not the case with, to take an example, contemporary biology. There is no established physical correlation between different levels of biological explanation of living organisms. We cannot, for example, explain the development of an organism or determine its place and status in the natural world by investigating the molecular level of the individual genes that constitute that organism. The structure and function of the fully grown organism is determined by a complex interaction between several genes and heterogeneous environmental factors. In order to explain and classify different species, the

biologist must rely on methods that may be incompatible with or irreducible to the methods of physics, such as personal judgment, intuition, and subjective perception (e.g., of the colored pattern in the wings of a butterfly). The same goes for ► [anthropology](#) and empirical psychology. To understand and explain human behavior requires methods radically different from those involved in explaining the function of, for example, the bladder. The different empirical sciences provide alternative methodological approaches to nature, and, by virtue of their different methodologies, they contribute to the general growth of scientific knowledge. Thus, in the eye of the critics, if methodological naturalism presupposes a unified scientific methodology, it is based on an ideological unity that does not reflect the actual nature and progress of scientific knowledge.

The notion of naturalism, therefore, still remains an open question in contemporary philosophy. Ontological (metaphysical) and methodological naturalism dominate this debate and elicit an intense discussion about the nature, status, and even legitimacy of philosophy among the empirical sciences. Some, including both philosophers and empirical scientists, believe that legitimate philosophical work must perform its analyses on the ontological foundation (of the world and the human mind) disclosed by the natural sciences and, moreover, that it must conform to the methodology of those sciences. Others maintain that such an uncritical acceptance of the superior status of the empirical sciences impoverishes, and eventually damages, philosophical arguments and methodology. Furthermore, the use of philosophy becomes limited, and philosophical analyses are reduced to fortifying certain scientific claims about the world, human nature, and proper scientific research instead of questioning the validity of such claims. In this way, the question of ontological and methodological naturalism stands out as one of the most radical and difficult issues in contemporary philosophy.

However, the notion of naturalism also plays a central role in contemporary research on the relation between science and religion. This entry concludes with a brief survey of the notion of naturalism in this field of research.

Naturalism and Religion

As we have seen, questions about religion and supernatural entities and phenomena have not been part of the philosophical debate about the concept of naturalism since the close of the nineteenth century. Such questions were handed over to theologians and philosophers of religion, who did not, for the most part, aspire to partake in this debate. Naturalism and religion did not seem to have much in common, and their paths only seldom crossed. This situation has changed drastically in recent years. Atheists and religious believers have exchanged some heavy blows in the form of both academic and more popular publications, debates in various media, and serious educational discussion. In particular, matters such as evolutionism versus creationism, brain versus soul, and, more generally, scientific versus religious meaning have dominated the debate. But whereas many believe naturalism and religion to be antagonists, some, both from within religion and the natural sciences, attempt to argue for a more integrative view known as religious naturalism. Religious naturalism can be considered an independent type of naturalism. Despite the fact that many contemporary religious naturalists find precursors to their position in the history of both modern philosophy (e.g., Spinoza) and ancient philosophy (e.g., the Stoics and the Skeptics), the term did not play a well-defined role in the debate between religion and science until about 1990 (Stone 2008). There are several varieties of religious naturalism, but this outline of the notion limits itself to some overarching features shared by all these varieties. Religious naturalists accept the fundamental view of both ontological and methodological naturalism, namely, that there exists no supernatural realm distinct from nature as we know it through the empirical sciences. Nevertheless, they argue that religious beliefs, experiences, and attitudes are a legitimate part of physical nature. Religion can be explained as a natural phenomenon on a par with other natural phenomena without any reference to supernatural beings or forces. All efficient causes are natural causes that can be

explained within a naturalistic framework. Physical nature as we know it is abundant in meaning and purpose and can therefore yield a depth and a meaning analogous to traditional religious experiences such as sacredness, peace, and wonder (Goodenough 1998). Contrary to common prejudices, a religious worldview is not necessarily antagonistic to a scientific worldview. The two may be complementary. Whereas the natural sciences uncover and expand our knowledge about physical nature (the universe, Earth, living organisms, and our own biological constitution), religion opens up an explanatory path into our spiritual world (meaning, values, love, feeling, ideas, dreams, and ethical standards) without compromising the laws of the physical world. The divine is not something distinct from this world and governed by supernatural laws and force. Religious naturalism complements science in the sense that it considers the complex whole of nature and the results that the physical whole produce. Science may help religion understand the nature of the divine and the nature of religious experiences and beliefs. Furthermore, science alone does not exhaust the meaning of nature. Many religious naturalists argue for an emergentist account of physical reality, where ► [consciousness](#), experience, and meaning are considered as the effects of various physical mechanisms, but cannot be reduced to these mechanisms; in short, there are more to physical phenomena than merely the sum of their parts and forces (Clayton and Davies 2006). The aim of religious naturalism is, then, to explore, explain, and legitimate the meaning of religion and religious experience in accordance with the insights gained by the natural sciences.

Notwithstanding the effort to integrate science and religion, religious naturalism is often criticized of not being naturalism at all. Naturalistic-minded philosophers do not see the need for religion and religious explanations, no matter how naturalized, in order to explain meaning or ethics in human life. Ontological naturalism without religion is just as capable of providing a coherent account of human feelings, joy, sadness, and ethical behavior. To introduce the idea

of religion in naturalism is, on this critical account, just to confuse the concept of naturalism and to open a way for superstition and unscientific arguments. On the contrary, religion and faith are not a complement to scientific explanations of nature and human life but simply expressions of an old-fashioned approach to life that needs to be examined in terms of a strict ontological naturalism (Dennett 2006). In spite of this critique, religious naturalism is continuing to develop as an alternative, more integrative, approach to the question about religion and religious experience in a naturalistic worldview disclosed and explained by the methods of the empirical sciences. The philosophical problems inherent in ontological and methodological naturalism are central to the future development of religious naturalism. Questions about the relation between phenomenal experience and physiological nature of the brain and the nature of reality and concepts such as transcendence, immanence, natural, and supernatural rely on proper clarification of the ontological and methodological status of naturalism.

Near-Death Experiences

Michael N. Marsh

Wolfson College, and The Oxford Centre for Christianity & Culture, Regent's Park College, University of Oxford, St. Giles, Oxford, UK

Description

Near-death experiences (NDE) and out-of-body experiences (OBE) describe a spectrum of subjective perceptions of an apparent dissociation between mind and body, usually resulting from extreme medical, death-threatening situations. They give rise to a “vision” of the self that is seemingly free of physical bounds.

N

Thinking About Life Beyond Death

Life terminates in death, a realization setting humankind apart from animals. There can be no doubt that our bodies eventually decay and become dust. But the prospect of what lies beyond death is intriguing to many. Traditionally, an existence beyond the grave has been articulated by the three Abrahamic faiths. Additionally, “new age spirituality” has come to offer an inventory of practices from aromatherapy to Zen thereby offering enlightenment to person, soul, or spirit. Third, the phenomenology of extracorporeal experiences (ECE), a term encompassing NDE and OBE, has attained popular notoriety. Although some ECE follow bereavement, depression, or severe loneliness, the majority, as noted above, result from acute medical crises which substantially embarrass brain function.

Near-Death Experiences, Fig. 1 For many subjects (*upper* schematic diagram) their extracorporeal experiences (ECE) terminate abruptly as full conscious awareness (*descending arrow*) resumes. For others, ECE rapidly taper, now being invaded by environmental percepts

(needle-prick or face-mask applied within hospital setting, etc.). However, as conscious awareness is quickly resumed, these latter intrusions are memorized and available for recall (lower diagram, area between vertical dotted lines)

This excerpt is typical:

I closed my eyes [and] never saw what happened when the car left the road... [it] seemed like eternity. Then... I was detached from my body... I was seeing my life flash before me... [then] a tunnel and a light glowing invitingly... I was encouraged to enter it. I was peaceful... I knew the answer to every mystery. Then... sudden confusion. I had to go back... I was upset, scared, thought of my family... earthly life. I was travelling... I regained my body... and felt tremendous pain. I believe I died: there is life after death... a truly wonderful "Heaven."

Many people therefore conclude that ECE phenomenology is confirmatory of another world, even "Heaven," as this victim herself believed. However, the particular word usage should not be overlooked: *near* death, not *actual* death. This entry examines the probity of several published ECE reports and asks whether these recollections truly demonstrate the existence of a veridical world beyond the known universe or whether they merely reflect aberrant brain functioning.

Logical and Empirical Analyses of ECE

The overriding difficulty about ECE is their personal subjectivity and thus how to get a firm handle on them. In a recent book (Marsh 2010), a reading of >700 transcripts offered a meta-analysis of canonical sources to

emphasize one crucially important insight – ECE terminates as conscious awareness returns (Fig. 1):

[I was]... in a crypt... waiting for my parents... Suddenly it was all gone – it ended abruptly... I felt tremendous pain and made a decision...

Or: The thing I remember most is a falling... I was coming down real fast and then hit... I woke up with a jolt.

These two "returns" occupied the moments immediately before resumption of conscious awareness. Neither person actually returned to corporeality, but their brains did regain full conscious awareness: that is the difference. As Kenneth Ring pertinently observed, "*Once the individual has returned, painfully or otherwise to his body, the... experience is over.*" He also queried: "*.... how exactly does one accomplish this return?*" – that is, reunite with body. But the question is what *needs* reuniting to body. Maybe nothing – only reawakening of the brain to full conscious awareness, a realization immediately dispelling one persisting mystery.

Secondly, having nailed how ECE terminates, duration is assessed by word counting, a technique employed by dream researchers in roughly assessing dream length. Counts for ECE reveal a duration lasting minutes – or even seconds – before conscious awareness is reestablished.

Thirdly, since it has been inferred that ECE occur rapidly as brains reawaken, the occurrence

of *memory* becomes explicable. Dead or dying brains cannot establish memories. If ECE occurred with moribund brains, as widely alleged, there could be no memories to permit recall. In sleep, memory is inhibited (hence the difficulty in dream recall) except for those intensely short, vivid dreams that occur on waking, so-called hypnopompic dream-awakenings which, phenomenologically, are virtually identical to ECE.

Fourthly, the conclusion inevitably arises that ECE are not vague journeys to an “ill-defined” somewhere, consequent upon mind, soul, or consciousness escaping a moribund or even dead brain, as asserted by writers critically reviewed (Marsh 2010). A strong claim that ECE reflect *brains recovering* from antecedent metabolic insult is therefore possible, manifested by subjects regaining full conscious awareness with memory for the event. Metabolic insult refers to common clinical emergencies (80%) such as cardiac arrest or severe hemorrhage, resulting in a prolonged period of very low-blood pressure impairing brain function.

Supporting Empirical Data

The logical progression outlined above asserts that ECE are transient events originating during those last frenzied moments of insult, when brains begin working properly, and subjects become fully conscious. There are firm, supportive empirical data which corroborate the foregoing assertions.

First, evidence comes from suicide survivors from the Golden Gate Bridge, San Francisco – an event lasting ~10 s. The (tidal) height to the walkway varies 250–260 ft, and for subjects of average weight, the fall takes ~4 s, the terminal velocity on entry being ~75 mph, survival depending on a head- or feet-first approach. Twenty subjects have been unsuccessful (of ~1,200 jumpers) since the Bridge opened in 1937 (Seiden 1968). Some could not remember entering the water, suggesting they were unconscious from impact: obviously they had to recover consciousness quickly to avoid drowning or freezing to death from cold immersion.

Second, from studies of military pilots losing consciousness during training sorties. Under laboratory conditions (Forster and Winnery 1988), they are centrifuged to unconsciousness while being heavily monitored. When subjects lose consciousness, centrifugation is stopped: recovery to full conscious awareness takes ~30–40 s.

Third, from laboratory-controlled observations on subjects deliberately making themselves unconscious – known medically as the “fainting lark” (Lempert et al. 1994). Again the follow-up period is relatively short, ~30 s.

What is so revealing is that during the recovery phase from each category of assault, subjects underwent transcendent episodes involving beautiful, vividly colored surroundings, saw deceased relatives, were deliriously happy, and enjoyed such highly emotive feelings that they were reluctant to “return to earth.”

These data present a series of varied reawakenings, but *from a preceding state of subconscious awareness* and over *measured time frames* (maximally 40 s), during which the phenomenology experienced hardly differs from ECE. When later interviewed, suicide subjects recounted evocative episodes of being in the light and at peace. The military investigators remarked that “*within such a very short period*,” pilots’ brains conjured up and remembered beautiful panoramic scenes. Clearly, mnemonic function returns very quickly as subjects’ brains recover from unconsciousness, despite post-centrifugation confusion.

Therefore, it can be concluded that the brain is extremely capable of manufacturing illusory states of a supposedly other-worldly realm, generated and acutely *remembered, recalled* over a very *short* measured time-frame, and arising from preceding states of reduced or absent conscious awareness. The phenomenology undergone is virtually identical and all of a piece with ECE. Four additional items need to be considered:

First, similar phenomenology is experienced while falling asleep, so-called hypnagogic hallucinations.

Second, the awakenings described are not associated with the fear of dying (and in the case of

suicidal persons, death presumably is the aim) unlike those undergoing cardiac arrest, during which one's innermost thoughts and fears of dying may be recalled from preexisting memory stores, hence coloring the phenomenology experienced.

Third, the reawakenings (above) are physiological, whereas the reawakenings from ECE would most certainly be abnormal, since the brain is recovering from a prolonged period of low (or even temporarily absent) blood pressure and perfusion. Moreover, given that most ECE follow a cardiac arrest, many subjects with advanced age would be suffering from well-established arterial atheroma. The bizarreness of ECE reportage could substantially reflect the fact that some brain areas or centers are beginning to function in the temporary absence of other controlling neural mechanisms and influences and subject to a reduced blood flow due to cerebrovascular disease.

The emerging conclusions are rational, logical, and supported by firm, empirical evidence, thereby avoiding fanciful, even desperate, speculative wonderings – if not wanderings.

Fourth, it is necessary to note that all retrospective reportage is loaded and bedeviled by erroneous perceptions and claims, often “manufactured” or “filled in” by the brain, and aligned to what sounds intelligible. This point is extremely valid, given that some subjects were reporting on occurrences several years or even decades previously.

Interrogating the Semantic Content and Quality of ECE Narrative

The empirical/logical analysis of ECE reportings, as outlined above, upholds their certain neurophysiological basis. However, other interrogational approaches can be employed critically to evaluate the type of language used and scenarios described, thus to determine whether the afterworld, eternity, or heaven had, in fact, been sampled during ECE. The semantic content of ECE reportage has never before been employed in this

manner: the following published excerpts are fairly typical.

First, a subject met his deceased father “...*dressed just like he used to be in grey trousers and a cardigan. He hadn't changed a bit. We chatted quite naturally and he joked. ...*”

The next subject explained, “*I found myself in front of a nice prefabricated building – the front door was open and mother was visible inside.*” Continuing, she notes that having brought some nice dress-making material, her mother put it on the table and prepared to cut it with scissors. The horrified daughter realized that her mother lacked dress-making skills. But her mother replied that since arriving, she was now being *taught* to be a seamstress. Then having been refused entry to the house, the daughter dejectedly returns home [presumably to earth].

A third woman agonized, “*I'm not staying here – [my husband] can't cope and I've left a pile of shirts to be ironed and he doesn't know how to do them.*”

This kind of material meant could hardly be regarded as serious, or to portray sensibly the supposed life beyond the earthly domain – wherever located. The matter recollected is geocentered, intensely anthropomorphic, and just plainly banal and as silly as dream contents. Second, it might be asked whether mind-dualists could accept these examples to uphold their claims that mind or consciousness can exist, presumably in a world of *sensible activity*, away from their underlying cerebral substrate. Third, similar sentiments apply to given descriptions of Jesus. Given His many appearances to several subjects at different times, we should expect to have accumulated a very accurate, uniform account of his appearance. However, descriptions vary and certainly do not reflect His true resurrectional majesty.

Here are typical reports,

I can see that form now – it had blond-gold hair ...and a beard – very light and a moustache [and] a white garment on – there was a red spot here [points to Sacred Heart on gown] – and a chalice in his hand.

And, “*He was tall – had a white robe on – his face was beautiful – his skin was glowing and absolutely flawless.*”

Again, “*She [mother] had a long sparkling gown on [as] did Christ – he had long hair – long beard.*”

Or, “*...there was Christ with a very white robe – he had jet black hair – very short black beard – teeth extremely white – eyes blue, very blue.*”

There is no necessity for informed literary criticism to detect the very boringly, this-worldly detail portrayed: in fact, just more dreamlike bizarreness and banality. In other words, nothing new has been revealed, only data acquired from previous earthbound experience – pictures remembered from Sunday school, childhood books, Hollywood, the media, fine art, and so on. Unfortunately, there is nothing novel, transcendent, heavenly – not even revelatory! – about these descriptions which seem to be utterly meaningless and valueless. Yet, these are the kind of descriptions which the canonical authors of ECE excitedly portray, even enthuse over and are seemingly taken in by. Moreover, it is very unlikely that this kind of material would convince an indifferent, skeptical public of the slightest possibility of an existence beyond known physical parameters.

Four additional points demand detailed, critical evaluation:

First: ECE accounts are nonidentical, nonuniform, and hence personally idiosyncratic. Such widespread idiosyncrasy is reflected in the canonical writings of several authors (see Marsh 2010) concerning the perception of the so-called “[L]ight”: 16% (Ring); 39% (Grey); 28% (Sabom); 43% (Greyson); 56% (Lindley); and 72% (Fenwick & Fenwick). Those vast differences are a little more widely distributed than one standard deviation – or two. Perhaps it should also be asked – maybe a little hesitantly – why the “other-world” is so *obstinately unequal* to those who apparently sample it. Were ECE to have anything to do with biblical outcomes, especially pertinent to the Kingdom of God, one might possibly expect everyone there to be equal: that is clearly not the case.

Second: ECE accounts are culturally determined – historically and geographically. Drychthelm’s journey recorded by the Venerable Bede in

Medieval England, ~800 CE, recalls Hell’s prescribed frozen wastes and sulfurous burnings as punishments for errant souls, while Heaven, just down the road (yes! literally within walking distance) boasts pleasant music, beautiful flowers, wonderful perfumes, and lovely people clothed in white garments enjoying a thoroughly well-organized events program. For modern Polynesians, Heaven comprises boats, cars, and other such commodities (Counts 1983). Those historic and geographic portrayals contrast sharply with the anodyne, soft loci of beautiful vistas, lovely flowers, and scented environments apparently sampled by modern Americans and British. Surely, such culturally determined reports must reflect on processes directly emanating from the brain since, as noted above, ECE arise most likely from injured brains during their return to full conscious awareness.

In parenthesis, we could profitably detour to consider some of the late Professor Alister Hardy’s data relating to his pursuit of a biological account of God. Hardy, who had been professor of Zoology at Oxford, saw religious experiences as ancient, even evolutionary, traits, and sources of great transcendental discovery and outreach, received and evoked through word, music, or painting – even science. Hardy anticipated moves from their purely observational reportings toward a scientific underwriting of these experiential typologies. As Evolutionary Theory had grown from the observations of Wallace and Darwin and Molecular Genetics from Mendel’s monastic peas so likewise, a “biology of God” could ultimately be realized, based on reported religious behavior and experiences – however ineffable. Hardy also recognized that a brain is necessary.

In “*The Spiritual Nature of Man*,” Hardy’s analysis of ~3,000 submitted accounts of alleged divine encounters (Hardy 1979) is extremely intriguing (see his Table II, p. 146) since it is unclear (a) why females predominate ~2:1 and (b) why their experiences peak a decade earlier than men, indicating a bimodal distribution. Furthermore, if the percentages for Hardy’s sensory-based “divine” experiences (visual, auditory, or tactile) are plotted graphically, they correspond

Near-Death Experiences, Fig. 2 The solid bars (*left hand*) represent percentage occupancies within the human cerebral cortex for the afferent functions subserving vision, hearing, touch (haptic), and smell (olfactory). The dotted bars (*right hand*) depict the

percentages from Hardy's book (1979, p. 26) of the frequencies of sensory perceptions experienced by 3,000 subjects as religious. These latter experiential data closely resemble the physiology of the normal brain

exactly to the percentage anatomical distribution of those sensory modalities within the cerebral cortex (Fig. 2).

In other words, for this large number of subjects, their experiential sensory perceptions of the divine exactly matched their physiological distribution across the brain. If these "spiritual" experiences were asserted to be completely external to, or even independent of brain physiology – that is, originating from outside, some difference might have been expected. It seemingly follows that the afferent sensory characteristics of "spiritual" life are similar, if not identical, to earthly experiences. On the other hand, the striking correspondence of Hardy's data to the anatomical cortical features of the brain suggests, perhaps, that for these cases, ECE do arise directly from the brain as the more likely explanation. It is a pity that such detailed data as presented by Hardy are entirely lacking in more recent canonical accounts of other-worldly phenomenology.

Third: it is clear that two or more experiences undergone by the same person are rarely identical. That is another grave problem confronting

those "experts" who assert that ECE are truly other-worldly events. This exemplifies another inconsistency in reporting, as with the variable descriptions of "Heaven" and of "Jesus."

Fourth: it is important to be aware of concurrent reception of *other-worldly* fantasy and *this-worldly* action – such as the sound of voices around the bedside, a painful injection, or the suffocating sensation of an oxygen mask applied to nose and mouth (Fig. 1). It is unlikely that a "dead" person inhabiting a so-called other realm (as others continue to assert) could simultaneously experience the commerce of this-worldly action. This dual type of conscious experience is not, of course, exclusive to *waking* ECE subjects: it occurs in lucid dreaming, auras with temporal lobe epilepsy, and drug taking.

The Out-of-Body Component

Much ECE phenomenology involves apparent motion: flying, ascending, floating, spinning,

and falling or bumping back into one's body: dreams likewise. This is referable to the "vestibular system," a complex brain organization creating a virtual image within conscious awareness of body shape (egocentric) and of its relationship to the immediate environment (paracentric space). This virtual image of the external environment is created through the amalgamation of multiple sensory inputs to the posterior parietal lobule (parietal lobe of brain). The common illusion of floating beneath the ceiling represents misperceptions of body position and a false projection of conscious awareness (Blanke and Mohr 2005). These misperceptions are short range within paracentric space and never extend to the horizon. Neurophysiological investigation has demonstrated the origins of OBE, experiences of a "tunnel," and of spiraling forwards or upwards into a light. Yet the tunnel illusion is shrouded in mystical overtones! However, for one meta-analysis (Drab 1981), only 10 % OBE reports referred to a tunnel caused in these cases by severe cardiopulmonary collapse. Tunnels are by no means a common accompaniment of OBE and hence certainly not to be regarded as possessing or implying some extraordinary "other-worldly" portent. It is especially noteworthy that as "laboratory fainters" regained conscious awareness, 8 % experienced tunnels and 16 % underwent OBE.

Subjects sometimes have reported on things or events impossible to have been witnessed from their resuscitative viewpoint, thus encouraging associations of OBE with "mystical" or "telepathic" qualities. Unfortunately, all such accounts lack hard and critical empirical data obtained and recorded through independent third-party surveillance *during the time of the resuscitation itself*. As far as is known, no writer has compared levels of increasing conscious awareness as measured, for example, with a BIS or equivalent machine (as sometimes used by anesthetists to gauge levels of surgical anesthesia), with the events later narrated by the subject and extrapolated backwards from the moment when full conscious awareness reemerged.

Testimony from OBE subjects is often patently false, as with Pam Reynolds. Reynolds

published worldwide her now famous account of being out of her body – through which she gained tremendous notoriety. Her account should be a "gold mine" for consciousness dualists. We know two facts: that she was anesthetized for more than 6 h (from her surgical notes) and her verbatim account totals ~725 words (as given 25 years later to Dr. Sabom: verbatim account reproduced in Marsh 2010).

The OBE (325 words) occurred while her head was being opened and although she declared that she was apparently "*sitting on the neurosurgeon's shoulders with heightened visual acuity*," Reynolds was absolutely wrong in her failure to notice that (a) her head was turned to her left and held there by strong mechanical brace, (b) it had not been completely shaved, (c) although viewing the operation from the surgeon's shoulders, she was unable to state *where* the bone saw was used although she heard it whirring, and (d) the use of the bone saw and femoral vein cannulation were concurrent: she alleged they were consecutive. Clearly, she was not out of her body on that fateful morning! Neither did the neurosurgeon report that an odd pair of female legs was dangling over his chest as he performed the craniotomy.

During her NDE (300 words), she was apparently fed "*sparkly stuff*" by her relatives: later, following her grandmother's refusal to take her back into the tunnel, she jumped into a swimming pool with her uncle – at the same time painfully reoccupying her body which felt like ice-cold water! But most curiously, as a result of that immersion, she was not dripping wet on immediately regaining consciousness in her bed, an occasion not apparently noticed by others – so far.

Most critically, we must demand where her mind/consciousness actually were during the 6+ h period of anesthetic unconsciousness and why she could not account for their activities while they were absent from her body, given that the sparse 725-word report offered contained remembered cerebral events which could not have lasted more than 5 min in real time. Moreover, the events comprising her extracorporeal experiences were wrong, unlikely, or even distinctly improbable. Surely a mind or

consciousness freed from physical (cerebral) constraints should be able to do better than that! So the critical question arises: what was her brain doing when it was supposedly outside her body for that long, blank period lasting approximately 6 h or more?

Unfortunately, it seems that Reynold's case provides neither exemplary proof for mind-dualists nor for "other-world" fantasists.

In another telling example, a young girl "imagined" going through a "momentary" period of external heart massage. In reality, her chest had to be opened to allow internal cardiac massage by a thoracic surgeon, a process requiring "several hours" to secure her life.

Again, no subject has ever successfully reported on marked cards placed near the ceiling of resuscitation units or lights or cupboards. Unfortunately, these attempts by hopeful investigators have failed dismally. It could be that subjects never were out of their bodies and therefore did not have the least chance of floating upwards to sample the experimental goods placed for them in high places. That is better explanation than Fenwick's rather weak response that subjects were far more intrigued by the complexities of their own resuscitations than to bother looking at specifically placed objects. Clearly, until we have some decent, properly collected data, contentious issues of this kind will always sadly persist to cloud and frustrate authentic understandings.

Nevertheless, the neurological basis of OBE occurring with NDE or other various non-death-related circumstances seems not to be in doubt: at least, that is one outcome to be sure of.

The Spiritual Contours of NDE Phenomenology

Beyond the rapid and vivid reawakenings to conscious awareness, the banal semantic content of the reportings given, and vestibular-generated motor accompaniments (OBE), ECE can be evaluated from the spiritual perspective. Classical

spiritual encounters have been articulated classically by William James and more recently by the American philosopher, William P Alston (Alston 1993), as follows:

One day when I was at prayer... I saw... or was conscious of... Christ at my side... I saw nothing with my eyes (S Teresa of Avila).

Or, "God surrounds me like the physical atmosphere. He is closer to me than my own breath. In him, literally, I live, move, and have my being."

And from S Richard of Victor

God sheds his sweetness... not his brightness... his beauty is not seen. He is surrounded by darkness... he does not appear in the light... [but] in the fire... the fire warms rather than illumines.

These quiet, almost evasive introspective reflections of divine encounter contrast markedly with typical ECE reportage which is considerably cruder:

I could see my mother and Christ saying, "Come home" and waving their hands at me. She [wore] a long sparkling silver gown and so did Christ – long hair, long beard – they were both smiling.

Or, "I heard his voice say 'Go back!.' I said 'Why me, Lord?' and whoever spoke said my work on earth wasn't over yet... all I heard was his voice: it was loud, thundering, just like a clap of thunder coming out of nowhere" [sic].

And, "I [was] in some type of building... pervaded by this beautiful light. Many people about me were milling about. I saw my parents... 'We've been waiting for you' – it was telepathic communication. I arrived at a place... I can only describe it as heaven... I felt enlightened and cleansed. In heaven, there is light, peace, music, beauty, and joyful activity, but above all, love."

These intensely anthropomorphic, geocentered reports recall Dr. Raymond Moody who so pertinently (but unwittingly) encapsulated the stark gulf between ECE experiences and classical accounts of divine disclosure: "Again and again, my ECE subjects have described to me a panoramic, wrap-around, full-colour, three-dimensional vision of the events of their lives..."

That last quotation sums up the position very well. Given such "spiritual" properties of ECE reports, one could hardly credit them with any serious divine import or revelatory content.

Overview and Revisionary Approach to NDE Phenomenology

This account of ECE is probably unique, markedly unlike the usual material served up for readers on this subject, and thus unexpected. Yet, given the approaches used – empirical, logical, semantic, neurophysiological, and theological, it is possible to conclude that ECE are manifestations of bizarre cerebration by brains emerging from fairly severe metabolic insults while regaining functional conscious awareness.

On those grounds, one could reject the views widely expressed by many authors and seemingly believed by their readership, specifically regarding the concept of “core” and “depth” ECE. ECE are quintessentially idiosyncratic brain-derived phenomena, reflective of individuals within their historic, geographic, or cultural settings:

1. There is no core or “*thanato-mimetic sequence*.” That is, no expected, invariant, consecutive experiential blueprint. Neither is there a death. Each ECE firmly emphasizes its intrinsic personal nature.
2. “Depth” is a mistaken confusion about ECE duration. The presumed length of an experience implies nothing about “depth” or “mystical significance” but simply reflects how many phenomenological bits and pieces constructed anew or sampled from its memory vaults are elaborated by each brain as it rapidly returns to normal working. From these new and original insights, an entirely new classification comprising **early-phase** and **late-phase** components (Table 1) can be envisaged:

The early phase largely involves vestibular components of floating, accelerating, traversing solid objects, or spiraling through a dark “tunnel” into “light,” indicating return of full visual cortical competence and ultimately of full conscious awareness.

The late phase comprises a sharp reluctance to cross any further solid barriers: thus, subjects signally refuse to journey beyond silly little obstructions (which they had no difficult traversing during the early outward phase) – bridges,

meadows, or garden fences. More importantly, there is a firm compelling moral compulsion to return to earthly duties and responsibilities, suggesting a final, “top-down” influence from the now recovering or functionally reconnected prefrontal cerebral cortex. Bumping back into the body sees the subject regaining a full sense of gravity (feeling very heavy and no longer weightless), somaesthesia (bodily pain, especially if the ECE results from accidental injury), and the reestablishment of full conscious awareness.

There can hardly be any surprise that ECE have never been the vehicles of revelatory insights into the other-worldly heavenly abode, what Jesus looks like, or as mirrors to the classical utterances of divine disclosure. It is clear that our ignorance about the contours of this supposed other-world continues, while the propositions offered herein are open to further neurological investigation.

The most intriguing aspect of ECE phenomenology is why so few subjects have them (~15 %). Furthermore, it is only this group, compared with many others who clinically come very near to death, who are changed in later life once having undergone ECE. It is hardly good enough to suggest that these people are touched by divine grace – albeit post-ECE subjects view life differently and enjoy greater rapport and loving relationships with members of their own families or other people. The markedly changed psychological profile of subjects emphasizes the need for the full clinical, neurological, and psychological assessments of all subjects likely to undergo ECE to be undertaken *before*, as well as *after* the event, so to permit valid, meaningful, and comparative (post-ECE) behavioral profiles. That is the proper meaning of a prospective study of ECE phenomenology: the results of such a desirable, critically controlled experiment are still expectantly awaited.

The relevance of that requirement follows from the possibility that susceptibility to ECE may relate to subclinical temporal lobe damage. For example, 1,096 young adults surveyed claimed to have experienced episodes consistent with underlying temporal lobe malfunction, due

Near-Death Experiences, Table 1 This table shows that NDE/OBE is more properly envisaged to comprise early-phase, and late-phase, phenomena. Precise classification is, of course, obscured by the marked idiosyncratic and unrepeatable nature of each experience. Listed are those prominent features of the early and later phases of ECE, thereby revealing that the so-called “core” and “depth” criteria employed by others are meaningless and inappropriate

Near-death and out-of-body experiences	
Early phase	Late phase
No pain	Feeling (injury-related) pain
Ability to traverse solid objects – walls, ceilings	Inability/unwillingness to cross physical barriers
Absence of gravity – “floating,” “weightlessness”	Bumpy return to body – sense of heaviness (gravity)
Sense of motion – acceleration, rotation	Reinhabiting a motionless body
Seeing a “light” and people	Hearing real voices or sensing contingent worldly events
No “moral” qualms when leaving family of friends behind	“Moral” urgency to return and resume earthly duties

to childhood head trauma and febrile illnesses and so on. Second, in another study, such episodes were controlled by the antiepileptic drug carbamazepine. Third, and more importantly still, in a smaller comparative study of control and ECE subjects, the latter revealed evidence on EEG traces, and through appropriate questionnaires, of subclinical temporal lobe damage (Britton and Bootzin 2004). Subclinical temporal lobe auras may possibly predispose a small number of subjects to the possibility of an ECE when undergoing stressful events later in life.

In order to advance this field, it is suggested that precise, incisive neurophysiological or neuropathological questions should be raised and dealt with empirically and prospectively, as with all good science. This entry has outlined some necessary procedures required, including the very vital assessments of likely subjects, *before* the ECE occurs. If, however, such questions cannot ultimately be answered through quantifiable, neuroscientific approaches as suggested herein, then indeed, there may be grounds for considering ECE to be one type of evidential demonstration of existence beyond the known universe.

There could, however, be validly held doubts about such eventuality.

Negative Theology

William Franke¹ and Chance Brandon Woods²

¹Vanderbilt University, Nashville, TN, USA

²Department of English, Vanderbilt University, Nashville, TN, USA

Description

The basic idea of negative theology is that of God, we can know and say only what “he” is not. Since God is metaphysically anterior to the world of intelligible beings, no predicate deployed within human language is capable of circumscribing him within the limits of signification. In the discourses of negative theology, everything that is said about *theos* is said under erasure and as cancelling itself out, since God is understood to be unnameable, unsayable, and indeed inconceivable.

The philosophical motivations for negative theology derive first from classical antiquity (especially in Plato’s *Parmenides*) and subsequently from the late antique developments of Neoplatonism in the writings of Plotinus, Porphyry, Iamblichus, and Proclus (Carabine 1995). These Greek writers sought foremost to elucidate how the first cause of Being remains ultimately inscrutable to finite human intelligence, and they demonstrated the incomprehensibility of the One beyond Being through logical means. Developing alongside these philosophical trends were, first, the Jewish belief in an absolutely transcendent deity (YHWH), emblemized in Moses’ encounter with God atop Mt. Sinai (Exodus 3:13–16) in clouded darkness, and, second, in the early Christian conceptions of Christ (Logos) serving as the revelatory word/icon of the hidden God (cf. John 6:46). Negative theology is a mode of human speech for signaling the elusiveness of God, where “God” can function differently in the various trajectories of ancient philosophy, Judaism, Christianity, and Islam.

Negative theology has been engaged by a number of thinkers in several traditions, but after the ascendancy of Jewish, Christian, and

Islamic culture in the Middle Ages, these three respective approaches have each engendered their own specific treatments of the ineffable God. It should be noted that if negative theology represents primarily the path of delineating what God *is not*, then differing identities of God (YHWH, Allah, the Trinity) receive correspondingly different manners of negation. Each tradition has manifested its own systematic outline of negative theology through the medieval, modern, and postmodern eras. Thus, while the several traditions often share a desire to limit the reach of human discourse *vis-à-vis* God, they each have developed their own idiosyncratic patterns of negation that should not be conflated indiscriminately.

Self-Identification

Science

To the extent that “science” denotes the process of fashioning a systematic study of all reality (biological, chemical, anatomical, cultural, etc.), it would be unfitting to describe negative theology as a science. Without calling into question the philosophical legitimacy of creating a comprehensive conception of reality, negative theology has tended to emphasize above all else that “God” cannot be located within such a scientific schema and, perhaps more importantly, that God’s ontological nature is not equivalent to that of discrete beings. Therefore, since we cannot know *what* God is, it would be fundamentally misguided to assign God a place within the order of beings studied by the different sciences. None the less, the philosophical underpinnings of negative theology suggest that negation is intrinsic to the very operations of human thought, even those that are systematized within organized methods of study.

Negative theology is at work in the negating function and dynamic of language in its essential character and from its very origins. It is operative universally throughout the whole extent of language, which is never without negation. Saying anything is always *not* saying something else. Since language operates on

a principle of difference, negation is a basic condition of sense. This condition is theological, furthermore, to the extent that the whole of reality and even the ground or source of reality is implicated in it: “reality” and the idea of its being “whole” themselves emerge only with language and its negations. The real is understandable only through distinction from the unreal and the whole only as not partial or fragmentary.

The real as a whole, moreover, is a theological conception, to the extent that it cannot be found as an item anywhere within the ambit of the sum of realities but transcends this order. In this sense, “theos” is not a distinct thing or entity but rather the always conjecturable ground or source presupposed by everything else – the condition of there being any distinct things or any reality whatsoever. Language first confers the conception of things as some kind of a grounded whole or universe, yet it can do so only by means of negation, since any item it can define and affirm cannot be the final ground. Negative theology is the self-critical thinking that brings this negative predicament of thought in language to consciousness and exposes its groundedness (or negatively expressed, its groundlessness) in the abyss of endless negation of everything that is any finite, definable thing.

Religion

Negative theology is a mode of reasoning and speaking endemic to many faith traditions (variously manifested, e.g., in Judaism, Christianity, and Islam), sharing also some philosophical registers with strains of thought from non-Western belief systems such as Taoism, Vedanta, and Buddhism as well. The Greek term *apophasis* (“away from speaking,” “negation”), upon which negative theology is based, has analogous terms in Hebrew, Arabic, Latin, and Chinese, though all are not purely identical in meaning. For this reason, negative theology is less of a religion *per se* and more of a form of theology that can subtend and suspend uncritical belief in any religion’s positive or primary discourse.

Characteristics

The relative uniqueness of negative theology inheres in its overarching disposition toward epistemology and the apprehension of God and existence by human consciousness. The whole of reality cannot be grasped as such, certainly not by a finite mind, without itself becoming something finite and limited and in fact, for that very reason, not whole. A truly universal whole cannot exclude anything else beyond itself. Only a whole that is broken open to its own “beyond” can count as truly universal, truly All, but in this case, such a whole is not definable except negatively – as including also everything that it is not but rather opens toward everything that can be projected as being beyond it. Only in this relation to its beyond is the whole really whole, and thus it is whole only in and as its own self-negation.

Accordingly, a whole and a ground of All without exceptions or exclusions can only be conceived of negatively. The whole in question is not one that can be grasped by any positive formula, since it is formed by negation. It is infinite. It is whole not because it can be encompassed conclusively but because it is broken open to the unlimited. It is an ungrasped, unencompassable whole. It must embrace – in the mode of opening itself toward – even what it cannot encompass or embrace. This includes the real and the unreal together, since any delimitation of “reality” would leave something out and not be truly all nor all-inclusive. Thus, this All has to be conceived of as the not-All. A notion of the not-All is developed by thinkers like Slavoj Žižek and Eric Santner with reference especially to Lacan, who writes of the “pas tout” and Rosenzweig, who thinks the “nicht Alles,” respectively. Only as not-All does it remain truly open to all that it cannot encompass or say in its own or in any language. It is rather the function of infinite openness to all through self-negation that is made possible through language. And this is the fundamental resource and source-spring of negative theology.

Indeed, like divinity, negation is infinite. Any notion negated – not A, for instance – opens to

an indefinable infinity of all that is not A. The “infinite” itself is transparently a negative conception. And likewise, any truly all-inclusive whole can be conceived of not positively (it could never encompass everything actual and possible) but only by negating all restrictions, exclusions, and limitations.

Thus, negative theology points to certain limits of all disciplinary discourses, their inability to circumscribe their domains and give an adequate account of themselves. It points to something undisciplinary – not capable of being reduced within the compass of any given discipline – and yet lying at the foundation of every discipline and every discourse (Franke 2007).

Relevance to Science and Religion

Theology, as the discourse of the unlimited, or as discourse without limits, turns out to be radically negative. However, this discourse is the revelation of a predicament that applies to the real quite generally. Negative theology, deeply considered, is not a specialized discourse or discipline to be ranged alongside others, each with a domain proper to itself and differentiated from others by criteria of exclusion. Negative theology invades discourse throughout its whole extent. There is always a factor of negation in discourse, since it *is not* what it says. And there are no limits to the capability of recursive self-negation of discourse: it reaches to infinity. This makes negative theology impossible to define. In fact, it does not exist, as Jacques Derrida lucidly maintained. There is no negative theology as such; there can only be a negative theology of negative theology: a discourse that cancels itself out by its very nature and necessity and that exists only in and as this act of self-annihilation or self-erasure. This is the case for negative theology in any of its ostensibly positive articulations – whether in Neoplatonic, Gnostic, Scholastic, or otherwise mystic discourses.

While negative theology functions to recognize the limits of discursive explanatory power, it should not be assumed that there is something radically antiscientific about it. Historically,

philosophers interested in negative theology’s ability to inculcate a devotional awareness of language’s finite power have concomitantly produced advancements in what is commonly called semiotics. In a sense, the underlying motivations of negative theology function as a science of signification. Thus, negative theology can function at the interstices of “science and religion” if both domains are understood to be modes of affording coherence to reality via language. Negative theology, in treating aspects of divinity, simply maps out the limits of language’s coherence when used descriptively of God. In the process, it gains even more traction on language’s conventional usage in speech.

Sources of Authority

Historically, the discourses most manifestly charged with testimony of this mysterious, self-annulling movement of thought and language that is constitutive of negative theology include monotheism and Neoplatonism and a wide range of mysticisms from the vedantic to the baroque and romantic. There are immemorial precedents in even more ancient mystery cults, in which silence was an essential step to initiation and illumination – for example, in the Eleusinian mysteries and among the disciples of Pythagoras, to cite just two classical instances. The broader anthropological background in primordial practices of shamanism, too, would surely furnish abundant parallels, yet without the same degree of critical self-reflectiveness.

Indeed, negative theology should best be considered to begin with rational reflection on divinity and with critical insight into the inescapable *aporiae* of all forms of its representation. This is developed systematically by the Neoplatonists through exegesis of precedents in Plato, especially in the *Parmenides*. And also the Jewish prophetic fulminations against idolatry open a similar vein of insight into the limits of all theological representations and become another foundation for negative theological reflection later in tradition.

There are important distinctions to be drawn between the different strands of negative theology through history (Olivetti 2002). As it was understood by its ancient philosophical expositors, negative theology was the deductive realization brought about through metaphysical speculation. For both Plato and Plotinus, since being is inextricably connected to intelligibility (i.e., to be is to be intelligible), then the “origin” of All (the One) can only be described in an analogous sense as the source of causality. Beyond this attenuated construction, the One must remain ineffable since it is impossible to allow the admixture of multiple predicates to our conception of the One’s radical unity (note that even “unity” fails in this case, as Plotinus suggests).

Without jettisoning the philosophical justification of negative theology, Judaism and Christianity had, in addition to these metaphysical insights, the warrant of inspired scripture that proclaimed the ineffable nature of God. In the Hebrew Bible, God has the unintelligible name of “I AM THAT I AM” (cf. Exodus 3), while the Christian New Testament bears witness to Paul’s mystical rapture to the third heaven where he encounters the ineffable presence of God, which he declares is forbidden to encapsulate in language (cf. 2 Corinthians 12). Revelation thus provides a supplementary impetus toward negative theology.

In the Middle Ages, both Judaism and Christianity would engender unique forms of negative theological speculation. Pseudo-Dionysius the Areopagite (fl. 500 C.E.), long held to be St. Paul’s direct disciple (cf. Acts 17:34), articulated a Christian Neoplatonic form of negative theology in his works *The Mystical Theology* and *The Divine Names*. Mosheh ben Maimon (Maimonides) systematized negative theology within Judaism in the twelfth century C.E. by arguing that no positive attribute could be predicated of God without risk of conceptual idolatry. Respectively, Dionysius and Maimonides would become the most authoritative voices of negative theology within Christianity and Judaism. They would in turn receive much commentary in the centuries that followed the dissemination of their writings.

Ethical Principles

First and foremost, negative theology is concerned with the ethical and moral orientation of the human mind toward God (conceived differently as the First Principle, the One, YHWH, the Trinity). From the perspective of Platonism and Neoplatonism, negative theology does not immediately engender an ethical awareness toward fellow human beings. Within Judaism and Christianity, however, the authorities of scriptural texts and doctrinal positions have coalesced to give negative theology a new valence of ethical awareness.

It is commonly held within Judaism and Christianity that humans are creatures made in the image of God (cf. Genesis 1:27). When coupled with the insights of negative theology, interesting ethical stances emerge from this belief. For instance, negative theology posits that God’s essence is incomprehensible in its very nature. If humans are made in the image of an incomprehensible God, then it follows that humans are, to some extent, incomprehensible in their very natures as well. There is thus something altogether indeterminate about both the nature of God and the nature of humanity. In the same way that negative theology seeks to deconstruct objectifying speech about God, it would follow that we should similarly call into question objectifying speech about human beings. Negative theology necessitates a more nuanced conception of personhood in our understanding of deity as well as our understanding of human psychology. Taken to its logical conclusions, then, negative theology fosters a heightened sensitivity to the incommensurable nature of persons, thereby eschewing degrading or disparaging speech about human beings.

Key Values

Negative theology is a way of thinking that is self-critical without limits. It can occur in all speculative discourses aiming at truth or meaning or sense. This sort of self-reflexive, self-critical

negation of oneself or of one's own discourse or affirmation may even be viewed as the ineluctable and necessary destiny of all reflective discourses aiming to expand consciousness without recognizing any intrinsic limits.

The importance and potential of negative theology as an overarching paradigm in our post-modern times (Halbmayer & Hoff 2008) lies in its offering ways of reading all the traditional and dogmatic discourses of religions and other ideologies less according to the letter of their ostensible affirmations and more in open receptivity to the enabling insights by which they are inspired and animated but which cannot be adequately expressed as such in articulate speech governed by binary laws of making articulate sense. The positive, dogmatic expressions of religions appear as exclusive of one another and are liable to create division and strife, even deadly conflict. However, in stepping back via negation (the *via negationis* or *via negativa*) from their own positive assertions, religious systems and visions are likely to find themselves inhabiting a common space that opens without restriction to infinity and divinity.

Conceptualization

As a theological process, negative theology eschews schematic definitions of discrete *aspects* of many things, especially as they are understood in relation to God. None the less, negative theology engenders specific theological orientations toward the domains of human categorization.

Nature/World

Pseudo-Dionysius the Areopagite, who is often considered the founder of Christian negative theology classically construed, coined the term *hierarchy* (*hierarchia*) in Greek to encapsulate his metaphysical understanding of reality (which he develops from the systems of the pagan writers Plotinus and Proclus). For Dionysius, hierarchy can be understood in ontological, celestial, and ecclesiastical terms. The levels within these hierarchies correspond to varying degrees of

participation in the ineffable God, who, despite resting beyond being, is the ground of all beings. According to the Neoplatonic tradition (ranging from Plotinus through Pseudo-Dionysius to Thomas Aquinas), since effects resemble their causes, then the first cause (i.e., God) must be approached metaphysically through the circumlocutions of negative theology. Therefore, negative theology enjoys a very specific conceptual relationship to causality within the natural world.

Human Being

As intimated above, given negative theology's emphasis on the incomprehensibility of God, the Judeo-Christian belief that humans were made in the image of God suggests that human nature is similarly incomprehensible. When the conception of human being is extended to include its bodily form, negative theology can be brought to bear on this as well. Ancient, patristic, and medieval understandings of negative theology purposefully eschewed dualistic frameworks of the mind-body relationship, positing on scriptural grounds that the body was essential for human nature (especially with regard to resurrection). Thus, negative theology, particularly in its more modern developments, has worked against a materialist or positivist construction of the human as merely body, for this would constitute another manner of objectifying speech about the corporeal form of humanity (Boesel & Keller 2010).

Life and Death

Death, like God, is treated as a name for the unnameable by numerous modern authors, Georges Bataille and Maurice Blanchot in particular, who draw upon and extend negative theological reflection. Life, too, because of the inaccessibility to experience of its origin (we do not remember being born) is treated as a mystery in a negative theological mode by authors from St. Augustine to Jean-Louis Chrétien.

Reality

The reality intended by any name ultimately escapes verbalization and is, finally, none other

than God, since in a monotheistic perspective only God is ultimately real: all other things are real only by virtue of participation in the one true Being of God. The reality named by all names, therefore, can be none other than God, and yet all names fail to attain the ultimate and divine reality, which remains, finally, nameless.

Knowledge

In its Neoplatonic and Christian manifestations, negative theology understands knowledge to be apprehension of discrete things or concepts. Indeed, since ontology and intelligibility function interdependently (i.e., to be is to be intelligible as an object of thought), then knowledge is the purview of a finite intelligence or mind. According to this logic, negative theology works against any putative suggestion that God could be an object of knowledge beyond the attenuated concept of causality. Even assigning God some agency as the first cause tells us nothing about the essence of God, which eludes all modes of knowledge. By calling God “infinite,” the negative theologian is not predicating any characteristic of God, but rather working through negation to suggest that it is impossible to subsume God into the categories of finite reality. Since God negates every discernable object of knowledge, then “knowledge of God” must be understood in non-intellective and nonpsychological terms. Throughout the Christian tradition, this modality of knowledge has been approximated as ecstasy, mystical union (i.e. with God), and transcendence.

Truth

There are innumerable names for the unnameable – indeed all names in some sense qualify. The apparent ban (in negative theology) on all discursive approaches to true divinity paradoxically yields inexhaustible streams of discourse relating to the mystery of the divine. Negative theology is, in fact, bound up with the extraordinarily rich culture and history of aiming at fathoming or registering the divine transcendence of every possible kind of discourse. However, even the conception of divinity as “transcendent” – like every conception – is

not strictly permissible for negative theology, except heuristically and provisionally. All themes and conceptions and contents are eventually transcended by whatever it is that drives negative theology.

Perception

In the Neoplatonic and Christian approaches to negative theology, Being is ineluctably tied to intelligibility. Plotinus and Pseudo-Dionysius routinely suggest that to be is to be intelligible. This means that human perception has a crucial function in marking the divide between the finite and the infinite. That which is intelligible is necessarily finite and therefore circumscribable within the ambit of human discourse. By contrast, the infinite (which, as the names signifies, is the total negation of finitude) escapes language. God is therefore legitimately called “infinite” only to the extent that such a description points toward God’s hyper-transcendent nature that eludes all intelligibility through perception. In a different cultural context, the Jewish prohibitions against idolatry work in a similar manner to emphasize that God’s authentic transcendence is not localizable in discrete objects or perceptible forms.

Time

What is left of negative theology, after this self-effacement, is its trace in history. Negative theology can only be glimpsed as a tradition, an archive, or a corpus of texts. As positive discourses, all these extant traces are no longer truly negative theology, yet we understand that they have been left in the wake of an impinging of the unthinkable upon thought and of the pressure of the unsayable against saying that has cancelled itself out as such by an intrinsic propulsion of its own constraining it to betray itself in some form of prolusion. This is why Levinas insists that the *Dire* is always betrayed by any *Dit*. We are thus able to read the negative theology in positively existing texts and discourses – to the extent that texts and discourses can positively exist, since in some sense they are always only projected by reading. Actually this ongoing activity of reading is never definitively localizable in place or time.

Conformably, negative theology itself never has any positive or fixed existence as such. It is divined always only in disappearing; it is grasped only to the extent that it escapes; it is present always only as absent.

Consciousness

Negative theologies in Eastern religions, particularly in Advaita Vedanta and in Mahayana Buddhism, in different ways turn on the realization of consciousness as an absolute reality – or on its extinction.

In Western Christianity, there is a discernable tradition of thinkers who posit that human consciousness and God's unknowability go hand in hand. These writers include figures such as Pseudo-Dionysius the Areopagite, John Scottus Eriugena (c. 800–c. 877), and Meister Eckhart (c. 1260–c. 1327). Thus, it is possible to articulate a form of apophatic anthropology (cf. Stang in Boesel & Keller 2010) that figures the mutual incomprehensibility of both God *and* person as fundamentally united in the ground of existence.

Rationality/Reason

These discourses of negativity across the ages and across disciplines and cultures are theological in scope, since they concern reality without limits and in relation to its projected and conjecturable grounds or origin. Negative theology is not irrational nor does it necessitate a fideistic stance in theology. While Judeo-Christian forms of negative theology often have as their goal the speculative protection and reverence for God's absolute or mediated transcendence, the logic of negative theology was first articulated in the rational discourse of Neoplatonic philosophy. Rather than occupying an antirational space, negative theology represents reason's deductive endpoint beyond which metaphysical speculation cannot venture without compromising the ineffable threshold of God's essence.

Mystery

The concept of mystery has much resonance with the enterprise of negative theology. Indeed, the founder of Christian negative theology, Pseudo-

Dionysius, encapsulated his philosophy most succinctly in his treatise *The Mystical Theology*. Etymologically, “mystic” means “silent” and derives from the Greek root *muein*, which signifies the closing of the lips to pronounce the consonant m. Within the Christian context, the Latinate word “sacrament” corresponds to the Greek term *mysterion*, which signals that which cannot be addressed in language. Thus, sacramental theology can be understood as the schema of ritualistic participation in the ineffable Godhead. While “mystery” points toward the disposition of reverent silence endemic to many faith traditions, it also gestures beyond the confines of specific doctrines through performative dramatizations of speechlessness. In this manner, while God remains ineffable, the human encounter with the mystery of his incomprehensibility can be performed through language (Sells 1994). Mystery then can embody multifarious indices of negative theology.

Relevant Themes

Negative theology is a form of critical thinking and even in some ways, its extreme development to the phase of an acute crisis of self-critical thinking that negates the very possibility of discourse, even its own. It began with Neoplatonic critique of all discourse concerning the One and continues through the anti-idolatry discourse of Critical Theory, especially in Theodore Adorno and Max Horkheimer. Negative theology can be seen as a self-critique of science that opens it to a religious dimension of the incalculable and ungraspable within its own bosom.

Neglect

Giuseppe Vallar and Nadia Bolognini
Department of Psychology, University of
Milano-Bicocca, Milan, Italy

Related Terms

[Spatial hemi-inattention](#)

Description

Unilateral spatial neglect is a neuropsychological syndrome caused by cerebral lesions which in humans typically involve the right cerebral hemisphere. Neglect has been described also in animals (monkey, cat, rat) with, however, no hemispheric asymmetries. Patients with neglect fail to orient to events (visual, auditory, tactile stimuli) occurring on the side of space

contralateral to the side of the lesion (i.e., the left-hand side in right-brain-damaged patients) and to explore it. Unilateral neglect is currently interpreted in terms of deficits of higher-level processes supporting spatial cognition: impaired orientation of attention toward the contralateral side of space or defective conscious representation of it, with attentional and representational accounts being not mutually exclusive. Spatial neglect is not due to primary sensorimotor deficits (e.g., visual disorders, hemiplegia). It may involve both the contralateral side of extra-personal space (“extra/peri-personal” neglect), the contralateral side of the body (“personal”), as well as internally generated images (“imaginal”). One component of the syndrome is unawareness (*anosognosia*) of neurological deficits contralateral to the side of the lesion (hemiplegia, hemianesthesia, hemianopia). These different manifestations of neglect are frequently associated but may manifest also in isolation, for instance, with patients showing extra-personal, but not personal, neglect and vice versa. These dissociations suggest that, although our phenomenal experience of space is unitary, the underlying processes are multivarious and may be selectively affected by brain damage (Bisiach and Vallar 2000; Heilman and Valenstein 2011; Husain 2008).

Self-Identification

Science

Unilateral spatial neglect has been first described in the medical literature published in the second half of the nineteenth century. Early brief clinical reports came from physicians specifically involved in investigating neurological and psychiatric diseases caused by brain damage: the Czech neuropsychiatrist Arnold Pick (1854–1924) in Prague and the British neurologist John Hughlings Jackson (1835–1911) in London. Subsequently, spatial neglect has been investigated in more and more detail, and it became increasingly clear that the deficit includes many components, which can present as selective deficits. This

suggests an articulated and complex structure of the spatial attentional and representational systems supporting spatial cognition. After the early investigations, performed in a medical context, the manifold behavioral manifestations of spatial neglect draw also the attention of many psychologists, including, among others, Oliver Zangwill (1913–1987) in Cambridge, UK. Since its inception, therefore, the study of neglect characterized itself as the description, assessment, and interpretation of a clinical medical disorder, within the domain of *neurology* and, subsequently, of *experimental and cognitive psychology*. The scientific features of the study of spatial neglect became more specific with the development of the scientific discipline of *neuropsychology*, which was defined in its aims and methods in the early 1950s. Neuropsychology aims at investigating the relationships between the mind and the behavior on the one hand and the brain on the other, combining knowledge and methods primarily from neurology and psychology but also from psychiatry and neurophysiology. The main, though not exclusive, source of empirical neuropsychological evidence has traditionally come from behavioral disorders in brain-damaged patients. Current neuropsychological methods include the following: on the neurological side, first of all a state-of-the-art assessment of the site and size of the responsible cerebral lesion by structural neuroimaging techniques, and investigations of the functional state of the damaged brain by functional neuroimaging and neurostimulation techniques; and on the behavioral side, a quantitative assessment of the pathological behavioral changes, through tasks based on cognitive models of the mind. In this perspective, spatial neglect is the object of investigation of brain (mainly neurology), and behavioral sciences, including connectionist simulation of behavior. One feature of the neglect syndrome is of interest for a discipline, outside medical and psychological sciences, namely, *philosophy*. One main feature of spatial neglect is the lack of perceptual consciousness of events occurring on the neglected side of space that are nevertheless processed. Secondly, patients are typically

unaware of their spatial neglect. Thirdly, the neglect syndrome includes other selective disorders of consciousness, with monothematic delusions. Patients may be unaware of and deny the presence of left-sided sensory and motor neurological deficits. In 1914, the French neurologist Joseph Babinski (1857–1932) definitely described unawareness for hemiplegia and coined the neologism *anosognosia* (from the Greek: *agnosia*, lack of knowledge; *nosos*, disease). Patients may also report delusional beliefs concerning left-sided body parts, which are experienced as not belonging to them. These deficits were systematically described by the Austrian and then North American neuropsychiatrist Josef Gerstmann (1887–1969), who coined the term *somatoparaphrenia* (*paraphrenia*: a psychotic syndrome characterized by hallucinations and delusions; *somato*: a prefix from Greek, meaning “body”: Gertsmann 1942). The selectivity of these deficits of consciousness suggests a multicomponent architecture of what may be termed the person’s *phenomenal conscious experience*, which, in the absence of brain damage, is reported as unitary.

Characteristics

The syndrome of unilateral spatial neglect is distinctive among other neuropsychological disorders in one main aspect. The deficit involves one specific sector of space which is most frequently lateral (along a left-right dimension) but may be also altitudinal (along an upper-lower dimension). The divide between the “neglected” and the “preserved” portion of space may apply to different spatial reference frames, namely, ego-centric, referred to the patient’s own body or body parts, and allocentric or object-based, referred to environmental or imagined objects. Even when neglect applies to representational domains such as language (*neglect dyslexia*, *neglect in spelling*) and numerical cognition (*a rightward bias in the mental number line*), its distinctive feature is a lateral bias toward the side of the lesion.

Relevance to Science and Religion

Characterizing unilateral spatial neglect as a spatially selective disorder of consciousness makes its manifestations of interest to philosophers concerned with the functional properties of the mind. Specifically, the empirical observation that these disorders of conscious experience may be selective (for instance, patients may be unaware of their left hemiplegia without showing left extrapersonal and personal spatial neglect and vice versa) suggests a multicomponent functional architecture of awareness of space and of the self. Pathological symptoms such as somatoparaphrenic phenomena, characterized by a disownership of left-sided body parts, often the hand, shed light on the organization of aspects of the self, such as ownership, from a neuropsychological perspective. From the vantage point of spatial neglect, the self includes a particular and unique 3D object in space (the body), surrounded by other animate and inanimate objects. This aspect may be of interest to religion.

Sources of Authority

The authorities in neuropsychological deficits are clinical and behavioral neurologists and psychologists concerned with cognitive disorders brought about by brain damage or dysfunction. After the first reports in the second half of the nineteenth century, in 1913, the Austrian neurologist Hermann Zingerle (1870–1935) described deficits of impaired perception of the body in right-brain-damaged patients, including left hemiasomatoagnosia, unawareness of left hemiplegia, and left motor neglect, and suggested that they might be due to an impaired representation of the left side of the body, caused by the right-sided lesion (Benke et al. 2004). In the 1940s, the British neurologist Walter Russell Brain (1895–1966) and the psychologist Oliver Zangwill reported symptoms of left unilateral spatial neglect after right-sided lesions. After the Second World War, spatial neglect was considered a clinical sign of damage to the parietal lobe,

particularly the right one. The neurological literature was summarized in 1953 by the British neurologist MacDonald Critchley (1900–1997) in the scholarly book *The parietal lobes*. In the subsequent two decades, many clinical and experimental studies on spatial neglect were published in neurological and neuropsychological scientific journals. The first book, specifically devoted to spatial neglect was edited in 1977 by the North American neurologists Edwin A. Weinstein (1907–1998) and Robert P. Friedland (1948): *Hemi-inattention and Hemisphere Specialization, Advances in Neurology, Volume 18* (Friedland and Weinstein 1977). Other books rapidly followed. In 1987, the French neurologist and neurophysiologist Marc Jeannerod (1935–2011) edited the book *Neurophysiological and neuropsychological aspects of spatial neglect*. In 1993, the British psychologists Ian H. Robertson (1951) and John C. Marshall (1939–2007) edited *Unilateral neglect: clinical and experimental studies*. At present, spatial neglect is discussed as a discrete and specific neuropsychological deficit in handbooks and textbooks of clinical neurology and neuropsychology. The sources mentioned above are as authoritative as can be scientific work in the domains of neurology, psychology, and neuropsychology.

Ethical Principles

Unilateral spatial neglect is a neurological and neuropsychological disorder. Seen in this perspective, as medical subdisciplines, neurology and neuropsychology are guided by the oath and law of the ancient Greek physician *Hippocrates* (born 460 B.C.) who is considered the so-called father of medicine. This “Hippocratic Oath” has been supplemented by the rules of the *Declaration of Helsinki* of 1971.

Key Values

A key value of neuropsychology, shared with neurology, is alleviating human *sufferings*,

understood as *disorders of the nervous system*, which lead to physical and mental impairments, personal dependence, and even death. Behavioral neurologists and neuropsychologists aim at developing and implementing diagnostic tools and therapies that are able to alleviate the patients' behavioral deficits, reducing their severity, both by enhancing recovery of the defective function and through learning of compensatory strategies by the patient. A related key value in neuropsychology is the counseling and guidance of patients during and after *acute* and *chronic neurological diseases*, which bring about neuropsychological deficits.

Conceptualization

Nature/World

Nature, in the broadest sense of the term, is conceptualized as the complete system of living and nonliving things. The world comprises the whole of things and the interspersed space of the universe. Right-brain-damaged patients with left spatial neglect are unaware of left-sided real-world situations and may perceive objects in the world as having no or corrupted left side, without noticing such abnormalities.

Human Being

The human being is conceptualized as a biological *being* equipped with a highly developed complex brain, and a body, which enables sensorimotor functions, and higher-order processes, including perception, action, speech, thinking and reasoning, creativity, ethics, morality, arts, and science. Unilateral spatial neglect is not specific to humans, but has been reported in animals, with, however, no hemispheric asymmetries.

Life and Death

In a broader sense, life is conceptualized as the property or condition of physical systems (*living systems*), with a higher degree of organization and complexity, with the *cell* being a basic unit. In living systems, a number of subsystems or organs constitute a *living organism*. Living

organisms, at variance with inanimate objects, have signaling and self-sustaining processes, with death being the cessation of them. In the human body, as well as in animals, these different organs include a *nervous system*.

Reality

Reality is the quality and condition of what is “real,” of things that actually exist, including our body and objects in the physical world around us. Our experience of reality, namely, of the whole physical environment which surrounds us, is subtended by discrete neural systems.

Knowledge

The term refers to the knowing, through experience and learning, of someone or something, as well as to the already acquired knowledge of people, objects, and facts. The acquisition and retention of knowledge are closely related to the multicomponent processes of memory and, more generally, to the whole of the cognitive and sensorimotor systems. Neuropsychological deficits may selectively impair components of the patient's knowledge.

Truth

Truth refers to the fact of being in accordance to reality or given principles. Statistical procedures may allow to estimate and recognize the “truth” regarding the reality of brain–behavior relationships, as investigated scientifically by neuropsychologist and behavioral neurologists (Zakzanis 2001).

Perception

Perception refers to the processes leading to awareness of events which stimulate our sensory systems. One main component of unilateral spatial neglect is defective perceptual awareness of events occurring in the neglected side of space.

Time

Time refers to the intuition and the representation of the fact that events take place in succession, so that some occur after and before others. With reference to the human experience, events belong

to the present (current), the past, or the future. Right-brain-damaged patients show defective estimation of time, and this has been taken as evidence that temporal processing involves spatial codes, with an important role of the right hemisphere.

Consciousness

Consciousness refers to the persons' awareness of themselves, including their bodies, and of the external world around them (i.e., objects and space among them). Spatial neglect may be considered a selective disorder of consciousness, of one side of space, and of objects in it, including the unique and special object of the body. Consciousness includes a number of discrete processes, which, under unimpaired conditions in a healthy individual, integrate into a coherent system, giving rise to awareness of the self as a unitary entity, distinct from objects in the external world. Spatial neglect may disrupt specific, spatially qualified, aspects of this awareness.

Rationality/Reason

Rationality is the quality of what is rational, a faculty of human beings who possess reason. Reason is the faculty of thinking, of relating concepts, as well as of distinguishing truth from falsehood, what is right from what is wrong. Reason includes judgment, discernment, and logic and is a foundation of accountable and responsible human behavior. Some aspects of reason may be impaired in component deficits of the neglect syndrome, such as anosognosia and somatoparaphrenia.

Mystery

Mystery refers to everything cannot be clearly and definitely understood and explained. Mystery may be considered to be contradictory to science, but it may be seen also as what is yet unknown or incompletely understood. However, the subjectivity of phenomenal experience may be regarded as "mysterious," as it cannot be accounted for, and explained in objective terms (see *subjectivism* vs. *objectivism*).

Conceptualization

A critical issue in neuropsychology, with reference to the relationships between "science" and "religion," is the notion of *subjectivity*. Subjectivism refers to views which, at various extents, reduce extramental reality to the way it is perceived and, more generally, known by the subject. In patients suffering from spatial neglect, the phenomenal experience of the outside world and the body is pathologically altered in ways that are only partially known by the experimenter, through the analysis of the patients' behavior and its neuropathological correlates. It remains possible that the patients' phenomenal experience, as subjective, cannot be completely understood, like that of every human being.

In a broader perspective, neuropsychology may also consider questions regarding how complex behaviors, thoughts, and feelings occur when they are associated with religious and spiritual experience and also by determining their underlying neural and cognitive underpinnings.

Neoplatonism

Victoria Ziva Frappollo
Department of Religious Studies, McMaster
University, Hamilton, ON, Canada

Any one of a body of philosophies of a religiously monistic type deriving from an interpretation of the works of Plato. Typically, such philosophies go beyond the doctrines contained in Plato's dialogues, introducing religious or spiritually based elements that result in the assertion of spirit as true being, with which is contrasted material and bodily reality. Such philosophies often contain ethical, devotional, and magical practices aimed toward the progressive liberation of the individual from the constraints of materiality and his or her reuniting with God, as the cosmic One, or true incorporeal reality.

Neopragmatism

Sami Pihlström
University of Jyväskylä, Jyväskylä, Finland

Introduction

Neopragmatism is not a unified philosophical school. Some leading (mostly American) philosophers have, since the 1980s, been described by this term, emphasizing their background in classical pragmatism (on which see the entry "Pragmatism," by Ulf Zackariasson). It is widely agreed that the two most important neopragmatists are Richard Rorty (1931–2007) and Hilary Putnam (1926–); other key figures include Joseph Margolis, Nicholas Rescher, and Susan Haack. The latter two have, in particular, sought to advance Charles S. Peirce's pragmatism, while the most famous neopragmatists have turned to William James and John Dewey instead. Moreover, some authors distinguish neopragmatism

from “new pragmatism,” suggesting that the latter need not be based on “old” pragmatism, despite thematic similarities (Misak 2007). It is often a problem whether the label “neopragmatist” should be attached to a particular thinker; occasionally, the word is used exclusively to refer to Rortyan pragmatism, while some use it broadly to cover different philosophical views influenced by the pragmatist tradition.

Classical pragmatism sought to reconnect philosophical theorizing with human practice. The pragmatic maxim, formulated by Peirce and James, advises us to consider what conceivable practical results our conception of an object may involve; our conception of such results *is* then our conception of that object. Neopragmatists share this general pragmatic approach to philosophical and scientific problems. However, a neopragmatist is not merely someone who studies classical pragmatism. Neopragmatists seek to apply pragmatist insights into contemporary problems, including the one concerning the relations between science and religion.

Like the classical pragmatists, neopragmatists have promoted the science–religion dialogue. While few neopragmatists are primarily philosophers of religion, neopragmatism as a philosophical framework is applicable to the problem of understanding religion and its relations to science. This entry focuses on Rorty’s and Putnam’s neopragmatisms, especially as they emerge as approaches to the relation between science and religion. Some other neopragmatist thinkers and ideas relevant to this topic are also briefly presented. The Rorty–Putnam contrast is, however, crucial for understanding neopragmatism, also because it is an opposition between secular and religiously engaged pragmatisms.

Rorty: Pragmatism as Antirepresentationalism, Philosophy as Cultural Politics

Giving Up the Very Idea of “Human Answerability”

Rorty’s neopragmatism is the best known both among philosophers and nonphilosophers. In

his book *Philosophy and the Mirror of Nature* (Rorty 1979), Rorty redescribed the history of Western philosophy in insightful ways, arguing that the problems of skepticism and the external world are “optional” and need not be taken seriously. Neither the mind nor language is a “mirror of nature” purporting to accurately represent external reality. Language – statements, vocabularies, and what Ludwig Wittgenstein called “language-games” – is a human invention, a collection of tools people may, pragmatically, use for various purposes. No vocabulary (neither scientific nor religious, for instance) is more intimately in touch with the way the world is “in itself” than any other; no linguistic framework is “nature’s own.” This is of profound significance for the science–religion dialogue. Language is used differently for different purposes; its goal is not to represent the way things are but to satisfy human needs and interests. Its main goal, then, is to help us “cope” with the world.

In later works, Rorty urges that pragmatists should enter a “post-Philosophical culture,” giving up “Philosophy with a capital ‘P’” (Rorty 1982); that *solidarity* is prior to objectivity and *democracy* to knowledge (Rorty 1991, 1999); that truth is not a goal of inquiry (Rorty 1998); that we should embrace an *antirepresentationalist* pragmatism, giving up the illusion of accurate representation (Rorty 1991, 1999) and an *ironism* suspicious of any “final vocabularies” (Rorty 1989); and that “cultural politics” should replace traditional philosophical inquiry (Rorty 2007).

Rorty was a radically secular thinker until the 1990s. His criticism of the metaphysical and epistemological tradition of Western philosophy is closely connected with his secularism: he has identified assumptions that have played the role that was in earlier worldviews reserved to God. Such is, for instance, the “absolute,” “independent” reality, the world *an sich*. According to Rorty, as humans and civilization grow more mature, such assumptions are given up. We should not think of ourselves as being “responsible” or “answerable” to any nonhuman power, divine or not. Accordingly, we should not base

our inquiries on the assumption that we are aiming at truth as accurate representation of independent reality. Thus, secularism is a key to Rorty's critique of Western philosophy; he has – to the dismay of scientific realists and naturalists – continuously argued that philosophers have not gone far enough in such secular attitude.

Rorty's *ethnocentrism* (captured in the slogan, "we have to start from where we are") is, however, close to *cultural relativism* (though Rorty denies being a relativist), leaving room for the autonomy of both scientific and religious descriptions of experience. Science is no more closely connected with the way the world is than religion – or any other human practice – is. People living within a religious *ethnos* have to start from where *they* are. Accordingly, Rorty does not maintain, as many atheists do, that scientific progress has made, or will make, religions irrational, unjustified, etc. He holds that modern people ("we Western liberals") would do better without religious vocabularies, just as they would do better without racist or sexist ones – or without the vocabulary of scientific realism and truth-seeking inquiry. Scientific realism and religious fundamentalism, Rorty (1999, p. 157) argues, are "products of the same urge" because attempting to convince people that they ought to develop an "absolute conception of reality" and attempting to convince them that they ought to "live 'for God only'" are "of a piece"; both are "attempts to make one's own private way of giving meaning to one's life – a way which romanticizes one's relation to something starkly and magnificently nonhuman, something Ultimately True and Real – obligatory for the general public."

Philosophy cannot adjudicate between the disputes of science and religion because it possesses no ahistorical "God's-Eye View" (Rorty 2003, p. 39). Secularism – or "anti-clericalism" – is not primarily a philosophical but a cultural-political issue (Rorty 2003, p. 39). The problem, according to critics, is that if Rorty's ethnocentrism leads to relativism, his neopragmatism lacks the normative resources of saying that this is what *ought to be* maintained.

Rorty on Hope

Rorty's attitude to religion slightly changed during his last years. It would be mistaken to call him anything else than secular in his late writings; yet, he authored several essays on religion in the 1990s and 2000s (Rorty 1999, 2003, 2007). This entry discusses the significance for the philosophy of religion of Rorty's view on *hope* as well as his suggestion that the question of religion is ultimately a question of *cultural politics* rather than philosophy.

Beliefs, including religious and metaphysical ones, are for pragmatists habits of action, inseparable from our practice-embedded being-in-the-world (to employ Heidegger's phrase), in which various hopes, fears, and other attitudes are inextricably present. We could hardly acquire *any* beliefs in the pragmatist sense unless we encountered reality in a context colored by hope, being oriented toward future actions which (we hope) may change the world. In a Peircean context, Elizabeth Cooke (2006) has argued that we need to hope that our questions are genuinely answerable for us to be able to inquire. Critics view Rorty's treatment of hope – for many, a paradigmatic neopragmatist picture of hope – as a trivialization of this concept. After all, Rorty's (1999) "philosophy of social hope" is part of his strictly antimetaphysical pragmatism: inquiry does not deal with the way the world is, but is a matter of conversation, replacing contingent vocabularies by other vocabularies.

In the three-essay set entitled "Hope in Place of Knowledge: A Version of Pragmatism" (Rorty 1999, Chaps. 2–4), Rorty proposes that hope should replace knowledge as a central goal and a key philosophical concept (cf. Rorty 2000). This is essential to the future-oriented approach of pragmatism, both classical and "neo." Because pragmatists "do not believe that there is a way things really are," they suggest replacing the reality–appearance distinction by the one "between descriptions of the world and of ourselves which are less useful and those which are more useful" (Rorty 1999, p. 27). Here the concept of hope becomes urgent because "useful" means "useful to create a better future"

(Rorty 1999, p. 27). Moreover, it is Rorty's own meta-level hope that hope would replace the pursuit of knowledge.

Neither realism nor theism leaves room for the right kind of hope, in Rorty's view. Citing Dewey's claim, made in 1903, that Ralph Waldo Emerson should be seen as "the philosopher of democracy," Rorty says, "Hope – the ability to believe that the future will be unspecifiably different from, and unspecifiably freer than, the past – is the condition of growth. That sort of hope was all that Dewey himself offered us [...]" (Rorty 1999, p. 120). He also speaks about "romantic hope" as a "willingness to substitute imagination for certainty, and curiosity for pride," connecting this to the Deweyan rejection of the distinction between contemplation and action and to the more general pragmatist rejection of the dichotomy between theoretical and practical approaches to reality (Rorty 1999, p. 88). He also notes that, with the romantics, history "began to replace God, Reason and Nature as the source of human hope" (Rorty 1999, p. 265).

Religion offers "hope for redemption through entering into a new relation to a supremely powerful non-human person," while philosophy offers hope for redemption through "acquiring a set of beliefs that represent things in the one way they truly are" (Rorty 2007, p. 91). Philosophers' "love of truth," the urge to get something (knowledge, mind, morality, or something else) "right," is the secular version of traditional religious hopes (Rorty 2007, p. 35). These hopes should be abandoned because in a "literary culture" both philosophy and religion are "optional literary genres" (Rorty 2007, p. 91). Again, the problem is how Rorty can argue for these hopes being wrong or misguided. How does his preferred view get its normative force?

Through his pragmatic hope, Rorty (2003) joins Gianni Vattimo's efforts to reinterpret the Christian tradition in terms of secularization, attempting to save religion from "ontotheological" metaphysical assumptions and doctrines: "To save religion from onto-theology you need to regard the desire for universal intersubjective agreement as just one human

need among many others" (Rorty 2003, p. 42). Rortyan hope is thoroughly secularized: "My sense of the holy, insofar as I have one, is bound up with the hope that someday, any millennium now, my remote descendants will live in a global civilization in which love is pretty much the only law" (Rorty 2003, p. 44). It remains unclear whether this admirable hope should be called "religious."

Nevertheless, many pragmatists undoubtedly applaud Rorty's emphasis on hope. In James's (1907, Chap. 3) pragmatic examination of metaphysical problems, there is also an implicit current of hope running through the discussion. Pragmatism, for James, "shifts the emphasis and looks forward into facts themselves," asking, "What is this world going to be? What is life eventually to make of itself?" (James 1907, p. 62). Metaphysical puzzles are not viewed as conflicts between complete, finished views. Rather, they are individual attempts to come to terms with different considerations reason may offer in favor of one or another way of interpreting experience. For instance, the theory of the free will (contrasted to determinism) is "a general cosmological theory of *promise*" and thus "a doctrine of *relief*" (James 1907, p. 61). Turning toward the future is as essential here as in Rorty's neopragmatism, and therefore hope also is.

However, Jamesian pragmatists may hold that hope should *not* be disconnected from metaphysical pursuits, as in Rorty's pragmatism. They may understand hope as a pragmatic way of approaching metaphysics, as an irreducibly ethical attitude to the study of metaphysical puzzles. A "Jamesian" neopragmatist attempts to make both metaphysics and ethics more relevant by reconnecting both with the hope for a better future. Such a metaphysically pregnant hope, which may, according to Cooke (2006), even play a "transcendental" role, being constitutive of any humanly possible inquiry or even thought, is "social hope," too, but not exactly in the Rortyan sense. Arguably, if such a social hope is genuine, then it is in touch with the way(s) the world is, from the perspective of the social practices engaged in, transformed, and redescribed by

those embracing it. Rorty's dichotomy between hope and knowledge is one of the dualisms he – as many critics have pointed out – is unpragmatically committed to, despite his pragmatic urge to destroy dichotomies.

Thus, according to Rorty's critics, his neopragmatism fails to sufficiently account for the role played by hope in inquiry, religious "inquiries" included, although his emphasis on this concept is relevant to neopragmatist philosophy of religion. Furthermore, Rorty's (1999, 2003, 2007) way of locating religion exclusively in the "private" sphere of individuals' lives, instead of the "public" sphere of common concerns, is also, for many critics, an utterly unpragmatist one. Pragmatists have, since Peirce, James, and Dewey, pictured the human individual as an individual-in-a-community, with no sharp separation between private and public issues. If religion is merely private, then, arguably, no genuine religious traditions – and, hence, no religious experiences either, if those experiences are "tradition-laden" – can arise. On the other hand, perhaps that is desirable from the perspective of Rortyan secularism.

Rorty's perspective on religion is, hence, resolutely antimetaphysical. Religion, like everything else, should be emancipated from foundationalist, essentialist, and ahistorical pursuits. "Literary intellectuals" and "ironists" should not only transform culture into a "post-Philosophical" one; they should also bring religious experiences, needs, and interests into a "postmetaphysical" era. Very little remains from traditional theism in such a "religion after metaphysics." Very little, then, remains from the traditional science–religion contrast.

The Question of God as a Cultural-Political Question

Rorty's atheism, secularism, or anti-clericalism can hardly be said to be a normatively defended or argued position, let alone a philosophical theory. In his last writings, Rorty emphasized the cultural-political status of his suggestions concerning religious (and other) ways of using language. Philosophical criticism of religion is, for Rorty, a matter of cultural politics, not

of metaphysics or epistemology. It is a matter of what kind of vocabularies should be maintained in "our" culture (and of how to define "our" culture or who "we" are). The meta-level issue of whether cultural politics should "replace ontology," as it in Rorty's view should, is itself a matter of cultural politics (Rorty 2007, p. 5), which is "the only game in town" (Rorty 2007, p. 8). The critical question is whether this view is coherent. Can Rorty consistently maintain that we should not argue for atheism or any other philosophical view?

According to Rorty, "the question of whether or not to talk about the existence of immaterial and infinite beings is not one of transcendental philosophy but rather one to be turned over to cultural politics" (Rorty 2007, p. 19). Debating over concrete political questions related to religious ways of life, such as whether female Muslim students should be allowed to wear veils on campus, is "more useful to human happiness" than debating over the existence of such beings (Rorty 2007, pp. 25–26). Furthermore, Rorty "drops" the idea that theology employs special kind of "symbolic forms," along with "the idea that God requires to be talked about in a special way because he is a special kind of being" (Rorty 2007, p. 22).

For Rorty, religion is a private matter: "our religion is our own business – something we need not even discuss with others, much less try to justify to them, unless we feel like doing so" (Rorty 2007, p. 25). He claims, controversially, that this is what "most intellectuals" today hold. Again, the critic who wonders how Rorty gets the normative resources to render his position plausible may point out that people, at least reflective people, have an intellectual duty to justify their views about religion or at least a duty to discuss those views as critically and rationally as possible with others. This is not to say that people ought to engage in evidentialist philosophy of religion, or in the religion–science debate. Yet, political issues surrounding religion can hardly be debated if religion is thoroughly privatized, moved beyond the public use of reason.

Rorty's account of religion as private is illuminated through his comments on *polytheism*.

Echoing James and Nietzsche, Rorty characterizes polytheism as the view that there is “no actual or possible object of knowledge that would permit [one] to commensurate and rank all human needs” (Rorty 2007, p. 30). This is comparable to Rorty’s earlier (1989) ironism about “final vocabularies.” Yet, for a truly religious person, such an account may sacrifice the seriousness of one’s commitment. Religion, for such a person, is not a matter of sheer choice, like the choice of clothes or a personal style.

Rorty’s most sustained account of a pragmatist philosophy of religion can be found in his essay “Pragmatism as Romantic Polytheism” (Rorty 2007, Chap. 2). He offers five theses (34–35): (1) Antirepresentationalism: beliefs are habits of action. (2) Romantic utilitarianism: there is no competition between science and religion, nor should one draw contrasts between cognitive and noncognitive or serious and nonserious matters or ways of speaking. (3) The distinction between projects of social cooperation and projects of individual self-development (largely paralleling the one between public and private matters) is important. (4) There is no “love of Truth”: “It is never an objection to a religious belief that there is no evidence for it. The only possible objection to it can be that it intrudes an individual project into a social and cooperative project, and thereby offends against the teachings of *On Liberty*.” (5) Religious fundamentalism is morally irresponsible, betraying the ideals of human fraternity and democracy.

This philosophy of religion is not identical to the classical pragmatists’. James, according to Rorty, *should* have said something like this: “[W]e are free to describe the universe in many different ways. Describing it as the drifting of cosmic atoms is useful for the social project of working together to control our environment and improve man’s estate. But that description leaves us entirely free to say, for example, that the Heavens proclaim the glory of God” (Rorty 2007, p. 36). James should *not* have talked about the literal and objective truth of religious beliefs but should have been satisfied with what he said in “The Will to Believe”: “we have a right to believe what we like when we are, so to speak, on our

own time. But we abandon this right when we are engaged in, for example, a scientific or a political project” (Rorty 2007, p. 37).

The problem here is whether reflective people, say, academics or intellectuals, should not *always* be “on their own time,” autonomous and independent. Rorty may not be able to encourage intellectual *responsibility* through his private–public dichotomy. When contrasting “one’s own time” to public, cooperative projects, he is, arguably, unpragmatic. The critic may point out that one should, even when cooperating with others in shared projects, be oneself, taking responsibility for one’s commitments.

Rorty prefers Dewey’s (1934) philosophy of religion to James’s because Dewey “was much less prone to a sense of guilt than was James” (Rorty 2007, p. 38). However, this sense of guilt may be what ultimately makes religion a deep issue in James, in a way it never is – from a Jamesian perspective – serious enough in Dewey. Rorty recognizes the role played by the concept of guilt in James’s pragmatism, but he overlooks the fact that this concept (or related ones, such as sin and evil) may be needed to make religion serious for James. If, “[i]n a democratic society, everybody gets to worship his or her personal symbol of ultimate concern” (Rorty 2007, p. 40), democratic worship may lack the kind of depth associated with religious ways of life. If everyone started to worship money as a personal symbol of ultimate concern, this would hardly be a religious activity.

Rorty’s neopragmatist perspective on religion may thus have difficulties in maintaining the seriousness of (especially Jamesian) pragmatist philosophy of religion in which guilt plays a strong role. Thus, it may have difficulties in accounting for the fact that religious faith is, for many, truly an “ultimate concern.” Another worry is that Rorty may have sacrificed the normative resources of critical philosophy of religion by reducing the problems of faith to a cultural-political clash of vocabularies. Such reductionism is not part of the classical pragmatists’ heritage. Rorty is not guilty of the “end of philosophy” line of thought sometimes associated with his neopragmatism because he does

maintain an important, though primarily cultural-political, role for philosophy (cf. Brandom 2000); yet, it remains unclear whether there is any critical, normatively structured way to discuss religion (e.g., in dialogue with science) seriously and argumentatively within Rortyan neopragmatism.

Putnam: Synthesizing Pragmatism and Realism

Metaphysical Versus Pragmatic Realism

Hilary Putnam's work on realism is a key element of neopragmatism. Indeed, neopragmatism has largely emerged from a critical dialogue between Putnam and Rorty on realism and truth. Both have subscribed to pragmatism, citing classics like James and Dewey; yet, they disagreed with each other about the significance of this tradition. Putnam has progressed from a scientific (metaphysical) realism through what he used to call "internal realism" toward a commonsense realism, or "cultivated" naive realism, which he claims to find in the philosophy of the later Wittgenstein (see Putnam and Conant 1994). In his critique of metaphysical realism, Putnam employs the views of Immanuel Kant, the classical pragmatists (especially James and Dewey), and Wittgenstein. Instead of detailed interpretations of these thinkers, he creates and recreates his own conception of realism and truth, including realism about religion, drawing inspiration from their ideas.

For Putnam (1981, 1990), *metaphysical realism* is the conjunction of three theses: (1) there is a way the world is in itself, mind- and language-independently, i.e., the world consists of a fixed set of mind-independent objects and properties; (2) the world can, in principle, be described in a complete, unique, and absolutely true representation (presumably an ideal scientific theory); and (3) truth is a non-epistemic notion, correspondence between linguistic items (statements, beliefs, or theories) and objects and/or states of affairs existing in the mind-independent world. Putnam's *internal realism* is, essentially, the denial of these theses. Claiming that the world can be correctly

described from multiple perspectives, reflecting our interests and purposes, internal realism is a version of the *pluralism* one finds in pragmatists like James and Dewey. The internal realist joins Rorty in urging that no description of the world, not even the most advanced scientific one, is the world's own. Descriptions available to us are grounded in human purposes and practices. Ontology, truth, and reference are internal to conceptual schemes serving different purposes. The upshot of this *conceptual relativity* is that we live in a human world; there is no "ready-made" world. It is, in Putnam's view, scientistic – culturally harmful – to view science as a superior language-game describing absolute reality.

In the 1980s, Putnam characterized truth as idealized epistemic justification, rational acceptability, or warranted assertibility, regarding truth as an epistemic notion contrasted to the non-epistemic correspondence concept of truth. More recently, he has noted that his epistemic theory of truth (and internal realism) was a misguided attempt to replace the unintelligible picture of metaphysical realism by a rival picture. We should, instead of succumbing to either metaphysical or internal realism, adopt a commonsensical "natural realism" (Putnam's other labels, "pragmatic realism" and "realism with a small 'r'," still apply to his views; cf. Putnam 1992; Putnam and Conant 1994).

The metaphysical realist's theses cannot, Putnam holds, simply be denied: we cannot affirm their negations because the negation of an unintelligible statement is equally unintelligible as the original one. The metaphysical realist does not, according to Putnam, reach for something (i.e., an absolute conception of the world) which is a meaningful goal and which we fail to achieve; our inability to describe the world absolutely is no failure because the very idea of such a description collapses into unintelligibility – as does the internal realist's view, if construed as the negation of such an idea. This change in Putnam's neopragmatism took place in the mid-1990s (cf. his 1994). It has a pragmatist background, insofar as he finds James's natural realism, along with Wittgenstein's focus on the "ordinary," among his sources.

The relevance of these reflections on realism to the philosophy of religion is obvious. Religious statements or (in Rortyan terms) vocabularies should not be conceived of along the lines of metaphysical realism any more than scientific or commonsense ones should. If any realism is acceptable, it must be “pragmatic” (Pihlström 1996, 1999). Moreover, scientific, commonsense, and religious (and other) perspectives on reality may contain some “truth,” and so do our moral worldviews; Putnam accepts no gulf between facts and values (Putnam 2002).

Putnam’s views on realism, especially internal realism, have been severely criticized both by realists affirming the existence of a mind-independent world and by more radical (Rortyan) neopragmatists who want to set the issues of realism and truth aside as fruitless pseudoproblems. It has been argued, among other things, that metaphysical realism is not an “all or nothing” affair: one can endorse one or two among the theses 1–3 above, without endorsing them all. Putnam, however, has stressed that it is unclear whether those theses make sense in the absence of one another.

Even though Putnam rejects the internal realism he initially propounded, he continues to think that the metaphysical (scientific) realist’s attempt to find a privileged (scientific) standpoint for describing reality in itself, independently of practice-laden perspectives, hopelessly fails. His attacks on strong realism have turned into general attacks on the reductionist, scientific dream of representing ultimate reality in terms of physical theory. Thus, his work on this topic has deep significance for the philosophy of religion. If scientism is rejected and no scientific perspective is treated as “absolute,” then religious perspectives are also allowed to enter critical, rational discussions. The pragmatist point here, echoing James (1907), is that both scientific and religious perspectives must be evaluated pragmatically, in terms of how well they satisfy human purposes.

It remains undecided whether Putnam’s rejection of metaphysical realism can be combined with a pragmatic (commonsense) realism affirming the objectivity and independence of

the world or whether it leads to a conception of the world as dependent on human practices. Putnam has been interpreted as a relativist or even an idealist, but he has reminded his critics that he never regarded the facts obtained in the world as dependent on how we use language (in any normal sense of “dependent”). Still, there is no privileged (scientific) perspective available for any absolute description of those facts. One option is to interpret Putnam’s view as “empirical realism” in Kant’s sense. The world is, according to such a (re)interpretation, constituted by purpose-oriented practices roughly in the manner in which the empirical world is a human construction, without being illusory or fictitious, according to Kant’s transcendental idealism.

Putnam’s views, in general, are thus a mixture of Kantian, pragmatist, and Wittgensteinian insights – and this holds for his neopragmatist philosophy of religion, in particular. There is a sense in which reality and truths about it are human constructions, but this does not entail a Protagorean relativism of individuals or cultures as “measures of what there is.” It is always from a purposive, practice-embedded point of view that we say whatever we say about the world we take to be real; following Wittgenstein, Putnam (2002) emphasizes the *context sensitivity* of meaning, justification, and rationality. It is only in particular contexts of philosophical bewilderment that, for instance, we are required to justify our beliefs about objective worldly facts. As there are several relevant contexts of investigation and justification, this view is close to pragmatic pluralism. In a religious or theological context – a context serving specific purposes – certain statements may be (held as) true, or rationally justified, even though they are not justified in a scientific context serving different purposes. Religious contexts do not require us to justify our views in the same way as scientific contexts do.

Putnam on Religion: Testing Ideas “in the Laboratory of Life”

Putnam has never been a secularist in Rorty’s manner, though it was late in his philosophical

development – only in the 1990s – that he began to reflect on his religious views philosophically (Putnam 1992, 1997). His neopragmatist treatment of the science–religion controversy integrates pragmatist (Jamesian–Deweyan) and Wittgensteinian insights. Together with Wittgensteinian philosophers of religion, Putnam argues that an evidentialist approach mischaracterizes religious faith. Religion is not a scientific theory intended to explain observable events; it is misleading to either support or criticize it on the basis of evidence (or lack thereof). Rather, religion is tied to deeply rooted forms of life within which we find significance for existence. Even if religious ideas can be said to be “empirically tested,” they must be understood differently from scientific theories. Religious views are tested “in the laboratory of life” (Putnam 1997a, p. 182), not in a research laboratory.

Some atheists maintain that “modern science has answered, or at least sketched a satisfactory answer to, *all* the problems with which metaphysics was traditionally concerned, and the answer simply leaves no room for religion [. . .] except as a historically and culturally important kind of *escapism*” (Putnam 1997a, p. 176). However, from Putnam’s pragmatist and Wittgensteinian perspective, the religious way of looking at reality is *not* “simply another scientific hypothesis, to be examined by the criteria of predictive accuracy, simplicity, and conservation of previous (scientific) belief” (Putnam 1997a, p. 178). Religious statements can be neither refuted nor confirmed by evidence. The materialist, reductionist, scientific critic of religion fails to understand what religion – the religious form(s) of life – is (Putnam 1997a, pp. 178–180). The religious fundamentalist commits the same mistake.

Religious responses to life are, for Putnam, varied, but the “potentiality” for making religious language one’s own is “a basic human potentiality,” and it takes “something experiential and not merely intellectual to awaken that possibility in a human being” (Putnam 1997c, p. 492). Religion should not be overintellectualized – as James argued a century earlier. Putnam, however,

reserves a role for intellectual discussion of religion in a way different from Rorty’s reduction of philosophy (of religion) to cultural politics. Putnam summarizes his account of how to philosophize about religion into three principles: (1) The Principle of Experiment: “Ideas must be tested in practice.” (2) The Principle of Fallibilism: “No human being and no body of human opinion is infallible.” (3) The Principle of Communication: “Truth is by its very nature public. Whatever your existential commitments may be, if you claim truth for them, you must be willing to discuss them” (Putnam 1997a, pp. 182–183). Following these principles is to be prepared to test religious views “in the laboratory of life.” While Putnam is sympathetic to Wittgensteinianism, he attacks “pseudo-Wittgensteinian ‘language-game theologians’” for giving up the possibility of reasonably criticizing religious beliefs (Putnam 1997b, p. 419).

How a rational critique of religion ought to be conducted on a pragmatic basis is, however, not obvious from Putnam’s writings. There is an element of existentialism and even mysticism in his position. He draws inspiration from negative theology, particularly Maimonides (Putnam 1997b), and ultimately regards religious ways of life as individuals’ deep personal commitments – resembling Rorty’s privatized religion. Characteristically, Putnam (1992, pp. 190–196) finds James’s perspective on religion superior to Dewey’s, though – in contrast to Rorty.

As another difference to Rorty, Putnam does consider religious ideas and commitments deep, profound, and ultimately significant. “There simply is no uncommitted place to stand with respect to the religious dimensions of human life,” he writes (Putnam 1997b, p. 408). Claiming to be “religious” is an “awesome responsibility” (Putnam 1997a, p. 185). The issue is existential in the sense of going deep into the very being of a human being: “*what it is to believe that God is personal and loves individuals depends on who one is all the way down and how one lives all the way down*” (Putnam 1997a, p. 184; original emphasis). How one uses the word “God” can only be explained with reference to who one

deeply is and how one leads one's personal life (Putnam 1997c, p. 498).

The basic difference between the two leading neopragmatists' views is that Rorty opposes (traditional) religious ideas, whereas Putnam is a "believer," a "practicing Jew." He even finds religious significance, though no sound philosophical theorizing, in the traditional proofs of God's existence (Putnam 1997c, p. 490). While in Rorty's case it is unclear whether, and how, the suggested cultural-political replacement of religious (e.g., Christian) vocabularies by secular ones could be normatively supported, in Putnam's case, the problem of normative force is slightly different. The problem now is whether his respect for individual, personal ways of living religious lives leaves room for any public discussion of reasons for preferring one such (form of) life to another. Putnam may in the end arrive at religious mysticism replacing rational argumentation by blind faith.

Other Neopragmatist Philosophies of Religion

Notably, neopragmatism has, over the past few decades, spread from the United States, the homeland of pragmatism, to Europe and other countries. Dirk-Martin Grube, a philosopher-theologian working in the Netherlands, has explored pragmatist themes in the philosophy of religion (Grube 2003), while Eberhard Herrmann, a theologian based in Sweden, has defended a "pragmatic realism" regarding religious belief indebted to Putnam (Herrmann 2003). Ulf Zackariasson (2002), in turn, has examined religion in the light of "pragmatic philosophical anthropology." European scholarly communities such as the Central European Pragmatist Forum and the Nordic Pragmatism Network attract philosophers and other researchers working on the science-religion dialogue. Thus, while the leading neopragmatists have been American, inheriting and critically developing the essentially American tradition of pragmatism (albeit with its European,

particularly Kantian and Hegelian, roots), this American way of thinking about religion is increasingly firmly established in Europe and elsewhere too. The cultural contexts for the science-religion debate are, obviously, quite different in these different countries.

Major Peirce and Dewey scholars have not focused on the philosophy of religion, however. It has mostly been the task of Jamesian pragmatists to continue religiously relevant philosophizing within the pragmatist tradition (cf. Pihlström 2008). However, the bearing of Putnam's and Rorty's neopragmatisms on the philosophy of religion still needs to be examined. The interpretation and appropriation of their positions in this regard have barely begun.

Moreover, pragmatist philosophers of religion work in close cooperation with other related currents, such as *religious naturalism* and *process philosophy* (including process theology). In some cases, it may be difficult to determine whether a particular thinker or position should be labeled "neopragmatist" or, say, "naturalist." Pragmatism is an open-ended tradition with flexible boundaries. It may be a sign of its vitality that it has been able to accommodate both religious and secular viewpoints, attracting thinkers from both camps.

Neuroethics

Kathinka Evers

Centre for Research Ethics & Bioethics (CRB),
Uppsala University, Uppsala, Sweden

Description

Neuroscientific advances and the challenges they encounter have inspired new academic disciplines. One is “neuroethics” concerned with the consequences, possible benefits, and dangers of modern research on the brain. It deals with our consciousness and sense of self, and the values that this self develops – it is an interface between the empirical brain sciences, philosophy of mind, moral philosophy, ethics, and the social sciences. It is the study of the questions that arise when scientific findings about the brain are carried out into philosophical analyses, medical practice, legal interpretations, and health and social policy. Such questions are not new; they were raised already during the French Enlightenment. Moreover, ethical problems arising from advances in neuroscience have long been dealt with by ethical committees throughout the world, though not necessarily under the neuroethics label. However, as an academic discipline labeled “neuroethics,” it is a very young discipline. The first references to neuroethics in the literature were made a few decades ago. Today, the pioneers of modern neuroethics have developed an entire body of literature and scholarship in the field of neuroethics that is rapidly expanding. So far, researchers in neuroethics have focused mainly on the ethics of neuroscience, or applied neuroethics, such as ethical issues involved in neuroimaging techniques, cognitive enhancement, or neuropharmacology.

Another important, though as yet less prevalent, scientific approach that may be referred to as fundamental neuroethics questions how knowledge of the brain’s functional architecture and its evolution can deepen our understanding of personal identity, consciousness, and intentionality, including the development of moral thought and judgment. Fundamental neuroethics should provide adequate theoretical foundations required in order to properly address the problems of applications. The initial question for fundamental neuroethics to answer is: How can natural science deepen our understanding of moral thought? How is the former relevant for the latter? One can see this as a sub-question of the question of whether human consciousness can be understood in biological terms, moral thought being a subset of thought in general. That is not a new query, but a version of the classical mind-body problem that has been discussed for millennia and in quite modern terms from the French Enlightenment and onward. What is comparatively new is the realization of the extent to which ancient philosophical problems emerge in the rapidly advancing neurosciences, such as whether or not the human species as such possesses a free will, what it means to have personal responsibility, to be a self, the relations between brain and consciousness, between emotions and cognition, or between emotions and memory.

Self-Identification

Science

Neuroethics is based on neuroscience and purports to offer combined philosophical and scientific explanations of important aspects of moral thought and judgment. While the understanding of ethics as a social phenomenon is primarily a matter of understanding cultural and social mechanisms, it is becoming increasingly apparent that the knowledge of the brain is highly relevant in the context. Progress in neuroscience, notably on the dynamic functions of neural networks, can deepen our understanding of decision-making, choice, acquisition of character and temperament, and the development of moral

dispositions. There is as yet no evidence of a dedicated moral-focused area in the brain, but ample evidence shows how brain dysfunctions or damages can underlie a multitude of cognitive, emotional, and behavioral disabilities, such as memory loss, attention deficit, or personality disorders, including moral incapacity. The brain is an organ of individuality – of intelligence, personality, behavior, and conscience – characteristics that brain science and neuroethics are increasingly able to examine, explain, and influence in significant ways. There are inevitable and important social consequences of the neuroscientific advancements, which may come to include profound changes in fundamental notions, such as human identity, self, integrity, personal responsibility, and freedom, but also, importantly, in neuroscience's own models of the human brain and consciousness moving away from modeling the brain as an artificial network, an input-output machine, to picturing it as awoken, projective and dynamic matter.

Characteristics

Neuroethics is simultaneously distinctive and interdisciplinary: it is an interface between empirical science on the one hand and abstract conceptual analyses on the other. It can be regarded and function as a discipline in its own right by virtue of its specific focus on neurobiological, social, and philosophical explanations of moral consciousness, judgment, and behavior; and on ethics applications of neuroscientific and neurotechnological advancements. However, neuroethics can also, by virtue of its interdisciplinary character, be seen as a sub-discipline of, notably, neuroscience, philosophy, or bioethics, depending on which perspective one wishes to emphasize.

Relevance to Science and Religion

Neuroethics is interested in religion primarily as a neurobiological and as a cultural phenomenon. Throughout most of the world, in different

cultures and historical eras, the human being has nourished religious beliefs, such as the dualistic belief in possessing a unique, and from the body distinct, soul. The natural sciences have questioned this belief from different angles, some of which are neuroscientific, with immediate relevance for neuroethics, which adopts a materialistic view on the mind. From the eighteenth century and onward, dualism came under serious attack as the natural sciences developed, suggesting that mental processes should be explained in physiological terms because consciousness is a bodily function. The idea of the mind as a biological entity gained ground, and the question how to understand the nature and origin of mind, and the relations between mind and matter became increasingly acute. The brain replaced the heart as the dwelling place of consciousness during the cephalocentric Enlightenment, and the question became how the mind and the brain are related, or how the brain gives rise to consciousness. Today, neurobiological analyses of consciousness investigate how the content of subjective experience is correlated with events in the brain. One aim is to gain a deeper understanding of the human mind, including its development of religion and morality. Neuroethics studies these neuroscientific advances. Neuroethics also takes interest in the various neurobiological explanations that have been suggested to religious experiences (an area sometimes referred to as neurotheology) and the hypothesis that there is a neurological and evolutionary basis of religious or spiritual experiences. For example, the use of electroencephalography or functional magnetic resonance imaging to localize brain regions that are active, or differentially active, during experiences that subjects associate with “spiritual” feelings or images.

Sources of Authority

Neuroethics is a purely academic pursuit and as a discipline in its own right it is quite young. It has as such no obvious sources of authority that stand out, but individual writers contribute peer-reviewed articles and books in different

countries. Neuroethics' sources of authority are the increasingly numerous individual scientists and philosophers who work in the field, and they are judged by the same standards as in other scientific or philosophical disciplines. A few of the authorities are suggested in the References.

Ethical Principles

The ethical principles that guide neuroethics are similar to those that guide other academic disciplines. They can basically be divided into two kinds: internal responsibilities related to individual conduct toward the discipline, the profession, students, and colleagues; and external responsibilities related to the impact of the discipline upon society. Concerning the internal responsibilities of individual scientists, ethical standards formulated in different disciplines and countries show a high degree of similarity. Five "core values" stand virtually unchallenged: honesty, skepticism, fairness, collegiality, and openness. The external responsibilities of neuroethics largely concern good use of the knowledge achieved, in particular avoiding civilian or military misuse. It should be observed that through its strong explanatory power, neuroscience could be regarded as even more controversial than genetics as a theoretical basis for ethical reasoning. Science can be, and has historically repeatedly been, ideologically hijacked, and more dangerously so the stronger the science in question is. A famous example is the development of evolutionary ethics developed in the nineteenth century, inspired by Charles Darwin's theory of evolution and natural selection, that can summarily be described as an attempt to base ethics on presumed facts about evolution that were not infrequently related to race. Knowledge of the brain can similarly be misused. If humans learn to understand and even design their own brain, that knowledge could be used well – on the other hand, the dream of the perfect human being has a sordid past providing ample cause for concern over such projects. Historic awareness is of utmost importance for neuroethics to assess

suggested applications in a responsible and realistic manner. Researchers in neuroethics have a joint responsibility to focus on realistic suggestions of future applications. In order to ensure that the ethical analyses are based on substantial scientific ground coupled with realism and conceptual clarity, studies in neuroethics should be construed as a threefold task involving scientific interpretation of theories and data, philosophical interpretation of central concepts, and ethical interpretation of problems arising in connection with applications and use. Ethical discussions can precede neither scientific nor philosophical interpretations.

Key Values

The general key values of neuroethics resemble those of other academic disciplines: seeking knowledge, facts, and theories with adequate methods and responsible applications.

Conceptualization

Nature/World

Neuroethics as an academic discipline defines nature as equivalent to the material world, which can include both mental and physical phenomena. It leaves open whether the world can also contain nonmaterial objects, notably abstract objects, such as numbers.

Human Being

Neuroethics defines the human being as a neuronal creature that is shaped both by its cerebral architecture and by the structures of the society and culture in which its brain develops. The human brain's functional architecture and human sociocultural structures develop in symbiosis, and they determine the nature of the human being conjointly. The structures of our societies influence our cerebral architectures, and the architecture of our brains determines the structures of the societies that we create. In that sense, neuroethics can be said to define the human being as a neuro-cultural creature.

Life and Death

Neuroethics defines life in the same manner as biology, which is the study of life: Living organisms have signaling and self-sustaining processes unlike inanimate objects. Death is the state that occurs when these processes have ceased. The aspects of human life and death that neuroethics specifically studies are both neurobiological and sociocultural.

Reality

Neuroethics basically conceptualizes reality in contrast to illusion or appearance, but there is no unique distinction that neuroethics draws in this regard. The realities which a human brain can create are multifarious and numerous, and while neuroethics studies them, the discipline has not an agreed definition of the term reality.

Knowledge

Neuroethics takes interest in knowledge acquisition and function. According to neuroscientific theory, knowledge acquisition takes place by means of cognitive games, in which the brain continuously, spontaneously, and autonomously produces pre-representations that the brain proceeds to test against other previously established models of the world, and against the environment in which it is operative. Pre-representations are selected as representations by reward signals, and models that are confirmed by both external evidence and internal processes of evaluation within the neuronal workspace itself are stabilized as permanent features ("representations") of the developing cognitive apparatus. The anticipation of reward introducing a delay between the elaboration of tacit plans of action and the actual interaction with the world performed by the organism is an additional component of cognitive learning, and a building block of the neural basis of morality. In contrast, a non-emotional system is purely passive and incapable of self-organization or evaluation; it can have no sensitivity to reward signals, and hence it would be incapable of learning, or of the development of moral thought and judgment.

Truth

The abstract philosophical concept of truth is not fundamentally a question for neuroscience, but the mental states of speaking the truth, or of lying, or the mental states of believing that one speaks the truth or lies, are of interest both to neuroscience and to neuroethics. Neurotechnological advances have produced increasingly sophisticated methods for testing whether a person speaks, or believes to speak, the truth, which is strongly relevant for neuroethics. The social, e.g., legal or military uses of such technology raise important ethical questions that neuroethics analyses, not least in terms of the adequacy of the interpretations of measurements that remain controversial.

Perception

The neuronal basis of perception is of high relevance to neuroethics that seeks to understand perceptual experience through studies of the brain functions. The area of vision is particularly interesting in this regard. Functional magnetic resonance imaging (fMRI) studies have shown that, based on patterns of activity evoked by different categories of visual images, it is possible to deduce simple features in the visual scene, or to which category it belongs. Recent studies take this approach a step further: a decoding method, based on quantitative receptive field models that characterize the relationship between visual stimuli and fMRI activity in early visual areas, can identify with high accuracy which specific natural image an observer saw, even for an image chosen at random from 1,000 distinct images. This prompts the thought that it may soon be possible to decode subjective perceptual experiences such as visual imagery and dreams. This research promises important new discoveries but also raises ethical challenges in application.

Time

Neuroethics does not specifically study time except in so far as it is an aspect of the human experience and consciousness. Humans experience time differently, but all have an experience of time; this is part of our neurobiological identity. This identity of experience is a research object for neuroethics and introduces time into

the area of neuroethics. Likewise, the concept of time constitutes an aspect of human nature. An important aspect of the individual cerebral perspective is temporal narrowness: it is extremely difficult, sometimes even impossible, for a human being to be emotionally concerned with, or clearly to envisage, actual or possible states or events that are temporally distant (e.g., imagined to lie one or several generations ahead in the future) compared to how we are involved with the present. Our cerebral structures are egocentric. This egocentricity is psychological, somatic, and spatiotemporal, which means that we, each of us, live in a minute and egocentric world: this-here-now (understanding the “now” as denoting a fairly wide personal time-perspective, since it is notoriously difficult for human beings to live in the “now” understood as the actual present). By nature, we are predisposed to do so. Neuroethics is interested in the nature and consequences of this predisposition.

Consciousness

Neuroethics starts with a by-the-common-sense definition of consciousness according to which consciousness is a state of awareness whether awake, or asleep and dreaming, of different degrees of intensity, and analyzes neuroscientific and philosophical views on this state. Neuroscientific research on consciousness seeks to explain the relationship between subjective mental states and brain states; it analyzes the nature of the relationship between the conscious mind and the electrochemical interactions in the body. This research combined with philosophy of mind form an important part of neuroethics. Neuroethics strives to shed light on the evolution of evaluative conscious minds, and also on the ethical issues that arise through this research. Developments in neuroscience and neurotechnology have opened the door to brain-machine interface communication without first person external behavior or speech. Functional magnetic resonance imaging is used to identify patterns of activity in the brain that suggest the presence of consciousness in people suffering from severe consciousness disorders and methods

to communicate cerebrally with patients who are motorically unable to communicate. It is also used non-clinically to access the contents of subjective experiences, such as emotions, or intentions via brain-machine interfaces. These new techniques hold promises of important medical breakthroughs and new knowledge about consciousness but also give rise to ethical concerns, notably in terms of health care and privacy.

Rationality/Reason

Neuroethics studies the neurobiological bases of reason and rationality and queries the connection with emotions without offering a determinate definition of rationality or reason. A part of the mind has to do with thinking, reasoning, and intellect; another part has to do with emotion. Emotion is an essential feature of value, and without any values a system cannot learn or remember: it has to prefer some stimuli to others in order to learn. Neuroscience is increasingly revealing the neural basis of emotion and cognition and a part of neuroethics focuses on this research. Ample evidence shows how brain dysfunctions or damages can underlie a multitude of cognitive, emotional, and behavioral disabilities, including self-indifference and social or moral incapacity. The ability to pursue rational self-interest, notably to understand a social situation and choose an appropriate action in the circumstances, depends on the architecture of the individual's brain.

Mystery

Neuroethics would conceptualize mystery as a neural-cultural phenomenon. It would seek to analyze the various neurobiological explanations that have been suggested to mystical experiences and relate them to the sociocultural role of the experience of mystery in different societies, religions, and historical eras.

Relevant Themes

Self

Neuroethics conceptualizes the self as an emergent phenomenon of our biology and studies this

phenomenon and its related aspects, such as the nature of the self, our self-conceptions, self-experiences, self-awareness, and self-interest. Applied neuroethics studies the ethical problems that emerge with our increasing scientific and technological capacities to manipulate or experimentally control the self.

Meaning

Neuroethics studies the narration of the human brain which is in constant quest for meaning: we continuously structure our experiences whether any meaning, or structure, “is there” independently of us or not. Numerous experiments have been performed showing that we do not seem to be biologically capable of perceiving, for instance, meaningless geometric figures, but that we construct patterns spontaneously from collections of random dots. To the extent that the dots are randomly placed without forming any pattern except in the eye of the beholder, one could argue that such patterns must ipso facto be perceptual illusions (since they supposedly do not exist independently of any beholder). Another way of seeing this is that such is the world that we experience and through our experience create, because our brains determine the nature of our environments that are not necessarily less real to the extent that we have influenced them. If we experience structure or meaning, then structure or meaning is there, at least on that phenomenal level. In that sense, meaning is a token of its own reality: it is there by virtue of being experienced. That does not mean that the interpretations are philosophically coherent or scientifically correct. Reality is a word with multiple meanings that can be applied to different levels of experience and explanation. Existentially, in the modern materialist models of mind, we are masters of the contents of our brains at least in some modest measure, and thus not to be seen as fettered biological machines operating automatically. We can accordingly influence our reality. Meaning can be created. This emphasizes the existentially and socially crucial idea that being a neurocultural creature is not incompatible with being in control over creating a meaning in our life,

experience, and world views. Meaning, sense, dignity, *raison d'être*, and other notions that human beings profoundly cherish are not lost to us because they are constructs depending on our cerebral architecture: on the contrary, we arguably thereby gain power over them.

Neuroethology

Jörg-Peter Ewert
Faculty of Natural Sciences, University of
Kassel, Schauenburg, Germany

Related Terms

[Behavioral neurobiology](#); [Neurobehavioral biology](#)

Description

Neuroethology is devoted to the experimental analysis of the neural (*neuro-*) fundamentals of natural behavior (*-ethology*). Neuroethologists seek to comparatively investigate neural systems of simple and complex organization both in invertebrates and in vertebrates with side glance to humans. Nervous systems are examined in the context of the problems they have evolved to solve. The tasks are diverse such as biosonar signal perception in mustached bats, auditory space perception in barn owls, visual prey recognition in common toads, electrosensory communication in weakly electric fish, or fear experience to noxious skin stimulation in sea slugs.

Questions central to neuroethology (Fig. 1):

- How are behaviorally relevant stimuli in the environment recognized by nervous systems?
- How are stimuli localized by nervous systems?
- How is information about a stimulus acquired, stored, and recalled by nervous systems?
- How is a behavioral pattern encoded, coordinated, and controlled by nervous systems?
- How do hormones and motivational states intervene in the choice and expression of behavior?
- How can the *ontogenetic* development of behavior be related to neural mechanisms, and are there *phylogenetically* conserved neurobehavioral principles?

Recent discoveries pertaining to the neurochemical basis of fear-response-related memory in the sea slug *Aplysia californica* – by Eric R. Kandel and coworkers – substantiate a significant perspective of neuroethology; knowledge of relatively simple neurobehavioral functions gained in phylogenetically lower organisms contributes toward our understanding of comparable complex functions in higher organisms including humans (cf. [Sources of Authority](#)).

Self-Identification

Science

Neuroethology self-identifies as a subdiscipline of neurobiology and belongs to the natural sciences. The research is addressed to the

experimental analysis of a neurobehavioral coherency (“black box”). The causation can be interpreted in terms of a hypothesis that allows one to develop a model. Models are predictive, pose new questions, and suggest investigations whose outcome leads to a specification or invalidation of the hypothesis. Aside from its intrinsic topics, neuroethology contributes *concepts* in view of therapeutic developments and *principles* suitable to implement in technical devices.

The accumulating knowledge in the field of neuroethology is treated in congresses and workshops of scientific organizations such as the *European Brain and Behaviour Society* (EBBS) and the *Göttingen Neurobiology Conference*. In 1981, the *International Society for Neuroethology* (ISN) was founded on the occasion of the NATO-Advanced Study Institute “Advances in Vertebrate Neuroethology” held at the University of Kassel in Hofgeismar (Germany). The first president of ISN was Theodore H. Bullock. The ISN has met every three years since its first meeting in Tokyo in 1986. Basic scientific journals include *Brain*, *Behavior and Evolution* and the *Journal of Comparative Physiology A*.

Characteristics

Topics of neuroethology overlap with basic research in *neurology* and *neuropsychology*. Various investigations require multidisciplinary approaches applying methods from *neurophysiology*, *neuroanatomy*, *neuroendocrinology*, *neurochemistry*, *neuroimmunocytochemistry*, *neuropharmacology*, *molecular genetics*, *neural engineering*, and *biocybernetics*. Progress in neuroethological research relies on the development of problem-oriented novel investigative methods.

Neuroethology is distinct from neurology and neuropsychology as it focuses on the neural basis of *natural behavior* in organisms of different organizations including invertebrates. Natural behaviors like feeding, mating, defending, escaping, and navigating emerged during evolution with a survival value for the individual and the species.

Neuroethology, Fig. 1 Schema illustrating some major neural operations mediating between a stimulus and an appropriate behavioral response: stimulus recognition,

stimulus localization, motivation, learning, commanding, motor pattern generation

Relevance to Science and Religion

Different worldviews are shaped by different *ways toward gain in knowledge*. Depending on the context, one such way employs natural sciences, another way, for example, calls for religions. Both are not mutually exclusive. We should be also aware that conceptions born in one such way (e.g., *soul*) may not be explored by methods from a different way (e.g., *neural network approach*). Such an attempt runs the risk of a “category error” (cf. [Relevant Themes](#)).

Different *ways toward gain in knowledge* are essential for multidimensional thinking. In such holistic reflection, for example, creationistic and evolutionary treatments – tackling similar topics in different ways – hold their own place values. According to a creationistic view, the species and the species-specific behavioral skills of organisms are explained by creation, for example, by an intelligent cause: “intelligent design.” Neuroethology explores species-specific behavioral skills in the context of the problems the underlying neural systems have evolved to solve, based on a process of natural selection. Of particular interest are solutions that – in terms of principles – were conserved during evolution. Well-studied examples in tetrapod vertebrates, from frogs to humans, concern the basal

ganglia (neural networks involved in motor control) and the limbic system (neural networks involved in motivation and learning). Another example concerns the genes *otd/Otx*, *Hox*, and *Pax* of the homeobox gene family that are responsible for the tripartite segmentation of the embryonic bauplan of the brains both in insects and vertebrates. The underlying genetic mechanisms suggest a common evolutionary origin.

Sources of Authority

Historically, two main research directions laid the foundation of neuroethology: ethology and neurophysiology. To the turn of the nineteenth century, the comparative exploration of animal behavior was born in conjunction with innovative conceptual analyses of pigeon behavior by Charles O. Whitman (1842–1910) and Wallace Craig (1876–1954). They examined whether Charles R. Darwin’s (1809–1882) theory of evolution applies to particular behavioral modes. Unlike the *behaviorists*, tracing their tradition to Ivan Pawlow (1849–1936) and studying principles of classical and operant conditioning in standardized, automated procedures (e.g., Skinner-box experiments), the *ethologists* seek to analyze naturally occurring behaviors and

to match the natural situation under controlled settings in the laboratory. The founding fathers of ethology – involving Karl von Frisch, Konrad Lorenz, and Nikolaas Tinbergen (Nobel Prize 1973) – developed important concepts which Tinbergen structured in his scholarly piece *The Study of Instinct* (1951). Later on, various ethological concepts like ► [key stimulus](#), innate releasing mechanism, and fixed action pattern were examined. The ideas contributed toward themes of neuroethological research. The textbook *The Behavior of Animals* edited by Johan J. Bolhuis and Luc-Alain Giraldeau (2005) offers an up-to-date treatment of ethology.

The founding fathers of neurophysiology include John C. Eccles, Alan L. Hodgkin, and Andrew F. Huxley (Nobel Prize 1963), who exposed the ionic mechanisms involved in excitation and inhibition in the nerve cell membrane, and Charles S. Sherrington (Nobel Prize 1932), who ascertained the phenomenon of inhibition as a coordinating principle in the nervous system. In the eye of the horseshoe crab *Limulus polyphemus*, Haldan Keffer Hartline (Nobel Prize 1967) discovered the phenomenon of lateral inhibition, a fundamental filtering principle developed also in other sensory systems both in invertebrates and vertebrates. Pioneers elucidating the neuronal information processing in the visual system and the specialization of the cerebral hemispheres in primates include David H. Hubel, Torsten N. Wiesel, and Roger W. Sperry, respectively (Nobel Prize 1981). Asking “What the frog’s eye tells the frog’s brain,” Jerome Y. Lettvin and coworkers (1969) examined feature detection by retinal ganglion cells in response to behaviorally relevant stimuli, hence tackling questions of neuroethology.

Neuroethology is rooted in the *Verhaltensphysiologie* promoted by Erich von Holst (1908–1962). Selecting three examples of his versatile ingenious research, he explored the principles of motor coordination of locomotion in various species. In collaboration with Horst Mittelstaedt, he discovered the reafference principle. Together with Ursula von St. Paul, he gained insight into the chick’s central nervous

framework of behavior motivations elicited by focal electrical brain stimulation. Walter R. Hess (Nobel Prize 1949) studied the subcortical organization in the cat with respect to the control of vegetative functions and the expression of emotion. He explored, for example, how to distinguish real rage from sham rage induced by electrical stimulation through electrodes in the hypothalamus. Theodore Holmes Bullock (1915–2005) – the leading neuroethologist in the twentieth century – promoted the investigation of neuronal responses underlying behavior patterns in various species of vertebrates and invertebrates toward a comparative approach.

Theodore H. Bullock and Erich von Holst are frequently referred to as the “fathers” of neuroethology. At the second half of the twentieth century, neuroethology was established in special working groups associated with universities or other institutions over the world. The first textbook under the title *Neuroethology* was written by J.-P. Ewert (1976, 1980). Target publications dedicated to neuroethology include P. Marler and W. J. Hamilton (1966), K. D. Roeder (1967), E. R. Kandel (1976), G. Hoyle (1977), D. M. Guthrie (1980), F. Huber and H. Markl (1983), R. R. Capranica (1983), J. M. Camhi (1984), N. Suga (1990), W. F. Heiligenberg (1991), T. H. Bullock (1999), P. Simmons and D. Young (1999), T. J. Carew (2000), M. Konishi and R. Menzel (2003), and G. K. H. Zupanc (2004).

A milestone in neuroethology is marked by the breakthrough in search of the neurochemical basis of fear-related memory by Eric R. Kandel (Nobel Prize 2000, shared with Arvid Carlsson and Paul Greengard for pioneering discoveries concerning signal transduction in the nervous system). Thus, a short extraction of part of his work is appropriate.

Kandel exposed the signal transduction in a neural circuit that enables the sea slug *Aplysia californica* to respond toward a mechanical stimulus with a fear reaction and to memorize fear. Upon touching *Aplysia*’s siphon, the gill is retracted. At first glance, the neuronal circuit underlying this kind of protective behavior

Neuroethology,

Fig. 2 Flow-charts of neurons involved in the fear response of *Aplysia* to touch stimulation.

(a) Stimulus-response mediating pathway; (b) synaptic sensitization via a modulating second pathway, referring to short-term memory; (c) synaptic growth as the basis of a persisting synaptic sensitization, referring to long-term memory. GM, gill motor neuron; IN, inter neuron; IN||SN, synapse between IN and the axonal terminal of the sensory siphon neuron, SN, that is responsive to touch; SN||GM, synapse between SN and GM; TN, sensory neuron of the tail responsive to noxious stimulation

looks like a simple stimulus-response connection; information flow from the sensory siphon neuron, SN, is transmitted synaptically to the gill motor neuron, GM (Fig. 2a).

With repeated stimulation, this fear response undergoes habituation until the reaction ceases. However, a noxious touch stimulus to another part of the body, for example, tail, immediately restores and even facilitates the fear response elicited via SN. The reason for this is that the synaptic transmission from SN to GM, at the synapse SN||GM, can be sensitized by signals of an interneuron, IN, whose axon contacts the axonal terminal of SN, thus forming the synapse IN||SN (Fig. 2b). Actually, that interneuron obtains input of a sensory neuron, TN, of the tail responsive to noxious touch (Fig. 2b). In short, two types of synapses are of interest here: a stimulus-response-mediating one (SN||GM) and

another one (IN||SN) that modulates, i.e., sensitizes SN||GM. Interestingly, the sensitization of SN||GM sustains the offset of the noxious tail stimulus in a manner of *short-term memory*. This results from the synaptic transfer at IN||SN that triggers in the axon terminal of SN a biochemical signal transduction cascade mediated by the chemical messenger cAMP which finally leads to a stronger neurotransmission at SN||GM.

Another signal transduction brings about the synaptic sensitization to persist. This *long-term memory* involves a dialog between synapse SN||GM and genes and hence relies upon transcription in the nucleus of SN; the messenger cAMP initiates activation of cAMP-response-element-binding (CREB) protein and transcription of cAMP-response-element (CRE) gene. That leads to (1) synthesis of growth factors,

(2) sprouting of synaptic axonal terminals, and (3) growth of the synapse SNII_{GM} (Fig. 2c). However, the gene transcription mediated by CREB1 is initially repressed by CREB2 so that an immediate access to long-term memory is blocked; unlocking CREB1 (by inhibiting CREB2) is prerequisite of long-term storage.

Furthermore, a protein CPEB at the amplified synapse SNII_{GM} fulfills two functions: firstly, labeling that synapse and, secondly, stabilizing the persistence of its sensitization. The stabilizing capacity of CPEB takes advantage of a “self-perpetuating” ► [prion-like](#) conformation of CPEB.

One of the important discoveries concerns the fact that long-term memory is based on new synaptic connections. As the neurochemical principle of memory derived from *Aplysia* is shared with mammals and may be akin to that in humans, this discovery promises to treat neurodegenerative memory deficits in humans by innovative medicaments. In progress is a new generation of *cognitive enhancers*, possibly acting by adjusting the cAMP level or the CREB1/CREB2 balance in the hippocampus, the key region of memory in vertebrates. The impact of the cAMP level for memory was checked in mice. Mice do not develop memory disorders comparable to Alzheimer’s disease. However, mice implanted with a human Alzheimer gene show weak memory and display deficits in synaptic axonal sprouting due to a low cAMP level in the hippocampus. Boosting the cAMP level pharmacologically in these transgenic mice stimulates synaptic growth and reduces memory disorders.

Ethical Principles

In neuroethological research, the ethical responsibility of humans to animals significantly accrues from the awareness that humans share with animals various connatural properties.

Experimental research in animals is supervised by authorities such as the regional *Ethics Commissions* appointed through laws of

animal protection, the *Multilateral Consultation of Parties to the European Convention for the Protection of Vertebrate Animals used for Experimental and other Scientific Purposes*, and the *Office of Laboratory Animal Welfare, OLAW*, at the National Institutes of Health, NIH, USA.

Key Values

It is a significant concern of neuroethology to uncover behaviorally relevant functions in the brains of animals of different organizations and differentiation and to derive common principles. Knowledge of neurobehavioral functions accessible in relatively “simple organisms” contributes toward our understanding of comparable functions in “complex organisms” including humans (cf. [Description](#) and [Sources of Authority](#)).

Conceptualization

Nature/World

Nature comprises all organisms and their environments (biotopes, ecological niches). The internal world of an organism, structured by its central nervous system, communicates via sense organs and effector organs with its external world, the environment. The central nervous system contains an image of the external world [cf. *Complex Worlds from Simpler Nervous Systems* edited by Frederick R. Prete (2004)].

Human Being

During evolution, the mammalian species *Homo sapiens sapiens* emerged in Africa (Ethiopia) about 195,000 years ago. Humans are equipped with a highly complex and differentiated brain. Although other organisms with complex brains may be superior to humans as far as particular neurobehavioral skills are concerned, humans are succeeding all by their linguistic peculiarities in syntax, semantics, and patterns of word formation. This affords abstract cerebration,

logic thinking, consciousness, reflection, and rationality – the prerequisites for ethics, religions, sciences, and cultures.

Life and Death

It is suggested that life emerged in the course of molecular and biological evolutionary processes. The criteria of life involve *set(s) of genes, reception, signal transduction (processing), metabolism, growth, and propagation (movement)*. Metabolism – catabolism and anabolism – maintains life. If metabolism ceases, the organism dies.

The concept of autopoiesis in the meaning of self-production is put forward by the neurobiologist Humberto R. Maturana to explain the nature of living systems. In this context, the term self-organization is used occasionally.

Reality

Reality is matched to an observer's perceptive faculty. The perceived reality depends on an individual's evaluation of the information flow received by its different *sense organs* and processed by its *brain*. For example, the biosonar-sensitive receptors confront the bat's brain with a reality that is entirely different from the one experienced, for example, by the human brain. Reality will change if certain processes underlying perception are interrupted. To a common toad after a pretectal brain lesion, the visual reality is quite different than prior to the lesion since every moving object – even an enemy – is perceived as prey.

Knowledge

Knowledge is a property that an individual acquires from perception, learning, memory, and retrieval during lifetime. Neurobiological correlates of long-term memory are newly linked contacts between neurons (cf. [Sources of Authority](#)). During lifetime, the number of neurons may decrease, whereas neuronal cross-linking in the memory-relevant brain regions – and hence wisdom – will increase. To avoid storage of irrelevant information and superfluous networking, selecting processes evolved

that prevent such information from long-term memory (e.g., CREB2, cf. [Sources of Authority](#)). In humans, memory and cerebration are prerequisites of the different ways toward gain in knowledge (cf. [Relevance to Science and Religion](#)).

Truth

The truth value of empiric data, for example, concerning the validity of a neurobehavioral coherency, is correlated with the reliability of the applied experimental measurements. The value that accounts for randomness and uncertainty in the measured data is expressed and quantified in statistic terms of probability. Furthermore, data referring to a causal connection can be interpreted by a hypothesis which again will be subject to experimental proof: verification or falsification.

Perception

Perception is a complex process of receiving, filtering, and binding. The process starts in the sense organs and proceeds in the central nervous system in a parallel-distributed and convergent fashion.

Time

In light-sensitive organisms – from cyanobacteria to humans – clock genes evolved that determine the circadian rhythm (biological clock) suitable to measure both local and elapsed time. Endogenous rhythm is synchronized with the photoperiod. Hormone levels (e.g., melatonin in vertebrates) distribute circadian information within the organism for diurnal changes in physiology and behavior. Time, on a large scale, is related to memory as the “binding agent” that mediates between *present* and *past* in the face of *future*.

Consciousness

Consciousness – self-reflection – presumes attention and requires a registration of perception, action, and imagination. In humans, both a present object *in Perception* and the absent object *in imagery* activate the same neuronal

systems. This demands a process that distinguishes between perception and imagination. If this process fails, hallucinations result, and self-reflection likewise self-confidence is disturbed.

Consciousness is also related to *empathy*, the ability of an individual to share perceptions, actions, and feelings of another individual without confusion of the two individuals. So-called mirror neurons, discovered in the frontal lobes of macaques by Giacomo Rizzolatti, are discussed as possible links to empathy. Mirror neurons are active when a monkey performs a certain task, but they also discharge when the monkey watches someone else performing the same task.

Rationality/Reason

Rationality is associated with reason and presumes insightful behavior of an individual which mainly results from various kinds of experience.

Mystery

Mystery denotes an enigma that refers to phenomena which cannot yet be tackled, investigated, and explained with our presently available causal analytical methods.

Relevant Themes

In view of the current advances in brain sciences, the question arises whether religion may lose some of its foundations if the conceptions are “deciphered” neurophysiologically someday. According to Otto D. Creutzfeldt, such appraisal comprises a significant error. In his book *Cortex Cerebri* (1983), he argues that humans can meaningfully reflect on their rationality and that they can effectually do this without knowledge about the neurophysiological premises of these reflections. The temptation, however, to interpret conceptions like *spirit* and *soul* in terms of specific neuronal activities proceeding in certain brain regions comprises a significant *category error* (cf. [Relevance to Science and Religion](#)) since the strategies of the brain, neurophysiologically, are different from the mental strategies of our rationality.

Neuroimaging

Rüdiger J. Seitz

Department of Neurology, Heinrich-Heine-University, Düsseldorf, Düsseldorf, Germany

Description

Neuroimaging is a technical discipline that visualizes the measurements of pathological changes in the *brain, spinal cord, nerves, cerebral blood vessels, and skeletal muscles* as well as of normal brain function in pictorial images. Neuroimaging comprises technologies such as *X-ray-based computed tomography, magnetic resonance imaging, positron emission tomography, and Duplex sonography*. Since its beginning in the early 1970s, neuroimaging has grown to a key diagnostic technology in *neurology, neurosurgery, psychiatry, neuropsychology, and cognitive psychology*.

Self-identification

Science

Neuroimaging has self-identified as a natural science because it applies the scientific methods of the natural sciences for clinical diagnostic procedures as well as for basic research. Neuroimaging is based on a mathematical algorithm which allows to calculate tomographic images from non-invasively scanned body parts. This algorithm was developed by Alan M. Cormack (1924–1998) and Godfrey N. Hounsfield (1919–2004) who were awarded with the Nobel Prize in 1979. Paul C. Lautabur (1929–2007) and Peter Mansfield (*1933) developed the basic principles of *magnetic resonance imaging*, which provides tomographic images of a large variety of physiological signals with high sensitivity and high

spatial resolution (Mazziotta et al. 2000). They were awarded with the Nobel Prize in 2003. The steady further development of the neuroimaging techniques and the increasing knowledge obtained by the clinical and theoretical applications is reflected by the formation of national and international scientific organizations such as the International Society for Magnetic Resonance Imaging (<http://www.ismrm.org/>), the American Society of Neuroimaging (<http://www.asnweb.org/>), and the Organization of Human Brain Mapping. These organizations run their regular scientific meetings and have their own scientific journals.

Characteristics

Neuroimaging is distinctive among other medical specialties by the laboratory character of its measurements. Also, the imaging technologies differ from other medical disciplines in that they allow virtually online insight into the body of a person (Fig. 1). Thereby, neuroimaging provides pictorial illustrations of normal anatomy and pathological changes of *brain, spinal cord, nerves, cerebral blood vessels, and skeletal muscles* as well as functional information of a large variety of biological variables including the *blood flow, metabolism, and distribution of neuroreceptors or neurotransmitters*. Also, brain areas involved in functions such as movements, perception, and language production can be identified (Toga and Mazziotta 2000). This is of interest not only in healthy people but also in patients with diseases affecting the ► *nervous system* with respect to how the *brain* is affected and adapts to neurological or psychiatric disorders (Toga and Mazziotta 2002).

Relevance to Science and Religion

Recently, attempts have been made by *functional neuroimaging* to bridge the gap between human brain *physiology* and cognitive and emotional control of behavior, decision making, communication, and *metaphysical* experiences. This interdisciplinary discourse between the neurosciences and the humanities is still in its infancy.

Neuroimaging,

Fig. 1 Example of neuroimaging findings using magnetic resonance imaging. (a) Impaired blood flow in acute stroke indicated by a delay of brain perfusion measured in seconds (*TTP*, red area). (b) Visualization of the intact large arteries supplying the brain with blood. (c) Acute brain infarction as demonstrated by an area with impaired water diffusion through the brain (*white area*). (d) Activation of brain areas related to a syntactic language task in a patient after recovery from aphasia following stroke

Sources of Authority

The authorities in neuroimaging are original publications in peer-reviewed scientific journals. With the advent of the Internet, electronic publishing and electronic libraries have become increasingly important. Of particular note are Internet-based databases, which can be used interactively to compare individual findings with the standard based on large cohorts.

Ethical Principles

As for every medical subdiscipline, neuroimaging is guided by the rules of the Declaration of Helsinki of 1971.

Key Values

The key value of neuroimaging is the objective and accurate visualization of the structure of the ► [nervous system](#) and of functional processes within the *brain, spinal cord, nerves, and skeletal muscles*. The underlying measurements are to be noninvasive with high spatial and temporal resolution.

Conceptualization

Nature/World

Nature is conceptualized as the *biological* and *biochemical* foundation of life on our globe. Nature entertains all dynamic processes in the observable environment. The world comprises the material and the interspersed space of the universe.

Human Being

The human being is considered as a biological *being* equipped with a highly developed complex brain, which enables unique functions including speech, abstract thinking, creativity, and the development of ethical categories such as morality, science, and art. Thus, humans are considered to be distinctive from the rest of the animal world in virtue of the unique capacities of the human brain.

Life and Death

Life is conceptualized as the presence of physical functions in biological systems ranging from bacteria over plants and animals to humans. In the human body it includes functioning of the different organs, including the ► [nervous system](#). Death is considered the cessation of such physical functions.

Reality

Reality is considered the physical world around us that humans can observe with their senses.

Knowledge

Knowledge is understood to have an *objective* dimension, such that it is the *wisdom* that can be transferred in a verbal form from one person to the next, or has been written down in books or libraries.

Truth

Truth is conceptualized as the supreme reality underlying facts and rules. Accordingly, truth is assumed to be absolute or universal, which humans can grasp only partially.

Perception

Perception is the *conscious sensation* of the forces and influences the external physical world exerts on living beings. Diseases of the human brain may disrupt or impair perception.

Time

Time is the fundamental category of ongoing change in the world. Humans can measure time *objectively* and perceive it owing to the changes observed in the surrounding environment.

Human perception of time can be affected by the focus of *attention* or impaired by diseases of the brain.

Consciousness

Consciousness is the responsiveness of subjects to any physical stimulus in the outside world. It can be graded in different levels of *alertness* ranging from drowsiness to full *alertness*, which comprises crystal clear orientation concerning location, time, situation, personal biography, and full mental capability. Diseases can impair consciousness globally, or in differentiated fashions.

Rationality/Reason

Rationality is a foundation of accountable and *responsible* human behavior and of understanding reason as ultimate authority. It is impaired in mental diseases such as *dementia* or neuropsychological disorders.

Mystery

Often mystery is considered to be contradictory to modern medicine including neurology. However, neuroimaging acknowledges in principle a place for mystery – that is, that which is as yet unknown – and thus grants that contemporary knowledge may not have elucidated the entire physiology of humankind. In this view mystery is understood as potentially explainable following the development of sufficiently advanced technologies of investigation.

Relevant Themes

A critical issue in neuroimaging as regards “Science and Religion” is the as yet unresolved question how expressions of religion can be investigated in humans.

³Laboratory of Biological Psychology, Department of Psychology, Katholieke Universiteit Leuven, Leuven, Belgium

⁴Department of Psychology, Centre for Cognitive Neuroimaging, University of Glasgow, Glasgow, UK

There are several imaging technologies. In alphabetical order, firstly, the *Magnetic Resonance Imaging (MRI)* uses nuclear magnetic resonance. F. Bloch (1905–1983) and E. Purcell (1912–) noted that atomic nuclei processing in the radiofrequency range could emit a radiofrequency signal that could be detected. In 1977, Damian and coworkers applied this physical principle to receive radiofrequency signals from different tissues of the human body. Secondly, there is the *Myelography* technology, which is used for indirect imaging of the spinal cord and nerve roots by filling the fluid spaces of

the spinal canal with a contrast agent. Thirdly, the *Positron Emission Tomography (PET)* is a highly specialized imaging technique that uses radioactive markers injected into the blood to produce 3D images of those markers functioning within the body. PET enables the location of metabolic activity to be visualized. It has high spatial resolution, in the order of centimeters, but low temporal resolution of minutes, hours, or days. Fourthly, the *Single-Photon Emission Tomography (SPECT or SPET)*, is a functional imaging technique that uses a gamma camera to detect a gamma ray-emitting compound that is introduced in living tissue. The distribution scan is superimposed on a tomographic 3-D image of the tissue. Then, there is the *Superconducting Quantum Interference Devices (SQUIDS)*, which is a highly sensitive sensors used in MEG systems for the measurement of tiny magnetic fields originating in the brain. SQUIDS operate at very low temperature (–269 °C) and require liquid helium for cooling. For more information on the *Magnetoencephalography (MEG)* as well as for, perhaps the most known technology, *Functional Magnetic Resonance Imaging (fMRI)*, see the separate articles on the subject matters.

Department of Neurology, Beijing Anzhen Hospital Capital Medical University, Beijing, P.R. China

Related Terms

[Neuroscience](#)

Description

Today, in Asia, neurology is devoted to offering detailed diagnostic criteria and therapeutic regimens for the clinical states and syndromes caused by diseases affecting the brain, spinal cord, nerves, nerve-muscle junction, and skeletal muscles.

Japanese Society of Neurology (JSN) was established in 1960 with 643 members, and in 2009 it grew up to a big society having more than 8,000 members including 3,600 neurology board specialists. JSN has greatly contributed in elucidating and resolving many sociomedical problems.

The first neurologic clinic in Korea was established in Jin-Ju City by an Australian doctor Charles Inglis McLaren in 1910. The first Korean neurologist was Dr. Lee Jung-Cheol. He studied and trained in China, Australia, and Japan and began practicing in 1934. The first department of neurology in Korea was founded as independent department in 1958 at the National Central Hospital in collaboration with Scandinavian countries. The development of neurology at Seoul National University was instituted in 1973. The Korea Neurological Association (KNA) held its first annual meeting in August of 1982 and was attended by 206 psychiatrists and internists. The first international academic meeting, the ninth Asia-Oceania Congress of Neurology, was held by the KNA in 1996.

The term neurology was coined in 1921 as an independent department in China, which became common in 1933. But at that time neurology was treated as a part of internal medicine or psychiatry in most hospitals. This development started in the university hospitals and was followed by the establishment of separate departments of neurology in most major community hospitals in the second half of the twentieth century. Till now there are some hospitals that do not have their own neurology emergency department, which may lose some patients. During the period 1966–1976, most neurology departments were cancelled for some reasons, and there were no academic activities, which had an impact on the

development of neurology in China. After that neurology has improved greatly in most fields.

The Society of Neurology became independent of the Society of Neurology and Psychiatry in 1994 and was organized similarly to any US or European professional association. The *Chinese Journal of Neurology and Psychiatry*, founded in 1955, was split into the *Journal of Neurology* and the *Journal of Psychiatry* in 1996. The Neurology Branch of the Chinese Medical Association has set up 13 working groups: (1) Dementia and cognitive disorders, (2) Neurochemistry, (3) Neuropathology, (4) EEG and epilepsy, (5) EMG and clinical neurophysiology, (6) Neurorehabilitation, (7) Neuroimmunology, (8) CSF cytology, (9) Parkinson's disease and movement disorders, (10) Neuropsychology and behavioral neurology, (11) Cerebrovascular disease, (12) Neuromuscular disease, and (13) Neurogenetics. The Chinese Neuropsychiatric Association, founded in 2007, is still in its infancy. The following describes, in large brush strokes, some topics in neurology that have a "Chinese face." More detailed reviews of sister disciplines, for example, neuropathology and neurosurgery, are available.

Self-identification

Science

Neurology has self-identified, from its very beginning, as a mysterious natural science. It has its special way of diagnosing complicated anatomical structures.

In ancient China, the oldest existing Chinese mention of disorders of the central nervous system, such as stroke and epilepsy, appeared in The Yellow Emperor's Inner Canon (Huangdi Neijing). This multivolume collection of medical tractates, comparable to the Hippocratic corpus, dates back to the first century BCE. The Canon's treatment prescriptions were based on the principles of rebalancing yin and yang and the Five Phases, and consisted of pharmaceutical herbs, acupuncture, massage, and physical and mental "self"-cultivation.

Before the first European visited Japan in 1549, traditional Chinese medicine was mainly employed in Japan. Touyou Yamawaki (1705–1762) observed the dismemberment of the corpse of a criminal in Kyoto and was surprised about the accuracy of the Dutch textbook. Soon he published “Records of Dissection” in 1759. After 1853, Western medicine was rapidly introduced into Japan, and great achievements by Japanese medical doctors soon followed.

Since the rapid progress of neurologic anatomy in the nineteenth century in the whole world, neurology in Asia has become an independent field. As the development of the human society, in 1921 the first organization of the human nervous system was founded. At first, neurology in China was greatly impressed by Russia. In the twentieth century lots of investigations resulted in innovations in the clinical field. First, the diagnostic procedure of neurology was divided into a localized diagnosis based on anatomy and a characterizing diagnosis, which is the definition of the disease. The gradually accumulating knowledge of the clinical syndromes is considered as an objective basis for a specific curative or symptomatic therapy. Second, concepts and practices of clinical investigation were developed in the twentieth century. There was great progress in neuroradiology for macroscopy and neuropathology for microscopy both of which were focused on the study of neuroanatomy. This helped neurologists to have more accurate localization and in some extent provided greater details of the character of the diseases. The effort of neurophysiology cannot be disregarded. The neurophysiologic investigations comprise electroencephalography, electromyography, nerve conductive velocity, and evoked potentials, which can evaluate the nervous system objectively and relatively across the board. Neuroimmunology was advanced in the end of twentieth century. The standard diagnosis was made according to it, which was used widespread. The neuromolecular biology and genetics in Asia has its own feature and pace. In the twentieth century, lots of theories were substantiated by observations in pathology of the nervous system and physiological studies in experimental

animals in the field of neurology in Asia. Then cell culture supplemented the scientific methods of the natural sciences for clinical and basic research as well as for diagnostic procedures and therapeutic regimens. Nevertheless, the pharmacochemical understanding of brain function is still in its infancy. This extended from the roles of the different neurotransmitters and their neuroreceptors for neurotransmission in the spinal cord to representations of brain function in the cerebral cortex and the subcortical brain structures including the interactions across these centers. In more recent time, multicenter randomized double-blinded studies have become increasingly important to establish common procedures among different countries.

Religion

Traditional Chinese Medicine (TCM) is worth mentioning here as it continues, at least in its modernized version, to be part of the Chinese medical landscape. However, as is often the case in China, without any official statistics it is difficult to obtain an accurate overview of the extent of the interaction between TCM and Western neurology. TCM is heavily influenced by the healing traditions of Taoism, one of the three major schools of Chinese religious philosophy. TCM posits that physical and mental health is based on a dynamic, harmonious equilibrium of internal and environmental influences. These include the two polar, complementary forces, yin and yang, the Five Phases (wu xing) and qi, the vital force that is both matter and energy (or neither, as Taoist thought just like quantum physics does not differentiate between the two) and flows through the body's dedicated energy channels (jing). Disease is caused by disruption of the balanced state, either in the form of excess, or deficiency. Treatment is aimed at restoring harmony, rather than the identification and eradication of a single pathogen. The history of neurology in China was a long story. Because of unknown and mysterious characters in neurology, some minority ethnic groups treat the diseases in special ways. Chinese traditional medicine is based on its own theory and experiences being different from religion. Up to the nineteenth century people recognized gradually that it was

a scientific discipline rather than a religion based on the rapid improvement of neuroanatomy and neurophysiology. There are different methods to evaluate the function of the brain, spinal cord, peripheral nerve, and muscle. The experimental proof or rejection of hypotheses, and the understanding step by step of the nervous system have told us it is not a religion any more.

Characteristics

Neurology is distinctive among other specialties of medicine in three aspects:

First, neurology aims to establish a strong relationship between clinical deficit patterns and the topography of lesion location within the nervous system, which was called anatomy localization diagnosis. This particular feature of neurology guides the neurologist in assessing the clinical abnormalities in terms of the pathophysiology related to the affected functional systems. Because of its complication, different foundation for Neurology is more complicated than the other disciplines. One millimeter lesion can induce various symptoms, like paralysis, eye movement disorder, dysarthria, dysesthesia, aphasia, and disorders of cognition and emotion that can be assessed objectively by the repertoire of clinical and diagnostic methods. This topographic organization is known to include the cerebrum, cerebellum, brain stem (the midbrain, the pons, and the medulla oblongata), spinal cord, the peripheral nerves, nervous-muscular junction, and skeletal muscles, as well as afferent fibers from sensory organs such as eyes, ears, nose, even the tongue. The disorders in internal medicine can affect the nervous system in a global manner leading to psychomotor slowing, apathy, or even coma. Also the nervous system involvement can be the first symptom or part of the systemic diseases.

Second, neurological diseases have complicated causes which are vascular, toxic, metabolic, hereditary, degenerative, nutritional, autoimmune, infective, neoplastic, and endocrine etiologies. Because the central nervous system can only incompletely regenerate, the degenerative diseases like Alzheimer's disease, Parkinson's

diseases, and amyotrophic lateralizing sclerosis cannot be cured now as they are different from the internal medicine diseases.

Third, neurology is a discipline which has tightest connection with psychiatry. The research of giving up drugs and alcohol by changing the neurotransmitters in the brain made good effect. The impairments in emotion and personality in patients in special situations are paid more attention now including depression after stroke, vascular dementia, temporal lobe and limbic systems injuries. Since other disciplines can have the same problems, the patient care in neurology necessarily is interdisciplinary.

Relevance to Science and Religion

In researches, we can see that the medical systems from ancient India, China, and Greek basically share the same inner structure and also the same logic of the treatment processes. Researchers analyzed the double concept of yin-yang, the Ayurvedic triadic concepts of Pitta, Kapha and Vata, the four elements of Hippocratic humoral medicine, and the five elements of Chinese medicine, and found that each of these conceptual frameworks make up a "theory" or model of the world that is a perfect wholeness, allowing the physician to interpret the world and his patient in order to identify the imbalances of his or her character that need to be treated. Independent of the system, this can be a palliative treatment if energies are only balanced in present time, or a causal cure if the physician is using the similarity principle to take his patient into regression back to the events in the personal history that originally created the imbalances (the traumas).

Religion, spirituality, health, and medicine have common roots in the conceptual framework of relationship amongst human beings, nature, and God. Of late, there has been a surge in interest in understanding the interplay of religion, spirituality, health, and medicine, both in popular and scientific literature. A number of published empirical studies suggest that religious involvement is associated with better outcomes in physical and mental health. Despite some

methodological limitations, these studies do point toward a positive association between religious involvement and better health. When faced with disease, disability, and death, many patients would like physicians to address their emotional and spiritual needs as well. The renewed interest in the interaction of religion and spirituality with health and medicine has significant implications in the Indian context. Although religion is translated as dharma in major Indian languages, dharma and religion are etymologically different and dharma is closer to spirituality than religion as an organized institution. Religion and spirituality play important roles in the lives of millions of Indians and therefore, Indian physicians need to respectfully acknowledge religious issues and address the spiritual needs of their patients.

In China there were few papers about religion and history in any medical discipline/subdiscipline. Though clinical complicated neurologic abnormalities and basic neuroscience phenomenon attracted most neurologists across the world, few neurologists paid attention to the history of this discipline. The improvement of neuroanatomy and neuroimaging gave us a concrete concept of nerve system including the peripheral and central nervous system. There was a religion of diagnosing in a scientific, rigorous, all around way of neurology, which is different from other disciplines. There is no scholarly area called "Science and Religion".

Sources of Authority

The authorities in neurology in Asia came in later than in Europe. The history of Western medicine in China dates back to 1805 when the English physician Dr. Hobson arrived in Canton (now Guangzhou). However, Western diagnoses and treatments of diseases of the nervous system were formally introduced only at the beginning of the Republican era (1911–1949) as part of the missionary project. Paralleling the situation in Europe and the USA, the early history of neurology in China is inseparable from psychiatry since most of the pioneers were practitioners of both specialties. In 1919, a prominent neurologist

from Philadelphia, Andrew H. Woods, became the first professor of neurology and psychiatry at Peking Union Medical College, a Rockefeller Foundation-sponsored university that was then the most prestigious medical institution in China. Two years later, Woods became the founding director of the newly established Department of Neurology and Psychiatry at Peking Union Medical College. The first academic society of the specialty, the Chinese Society of Neurology and Psychiatry, was founded in 1931.

In 1921 Beijing had its independent neurology department to teach neurology, which was established in other areas after 1933. In 1952, Chinese Medical Association Neuropsychiatry society was founded. The first magazine called *Chinese Journal of Neuropsychiatry* was published in March 1955. From November 25th to December 2th, 1963, the first neuropsychiatry academic conference was held in Guangzhou which received 312 articles about acute cerebral blood circulation disorders, epilepsy and brain tumors. At that time, DSA, electroencephalography, ultrasound, and isotope test were progressing rapidly. In 1994, the Chinese Medical Association Neurology Society was founded with nine groups including the electromyography and neurophysiology group (1984), neuropathology (1986), neurobiology (1986), electroencephalography and epilepsy group (1987), neuropsychiatry group (1987), neuroimmunology group (1989), neuromyopathy group (1991), neurerehabilitation (1991), and cerebral spinal fluid cell group (1991). The first edition of the Chinese Journal of Neurology was published.

The first medical society of Japanese neurologists and psychiatrists was founded in 1902, but psychiatrists gradually dominated in number. New "Japanese Society of Neurology" (JSN) was founded in 1960. The number of members was only 643 in 1960, while it rose up to 8,555 in 2009, including regular, junior, senior, and associate members. JSN contributed much to solve the causes and treatment of the medicosocial and iatrogenic diseases such as Minamata disease and SMON (subacute myelopticoneuropathy) at its early period. In undergraduate education at medical school, neurology is one of the core subjects

in the curriculum, and almost all the 80 medical schools have at least one faculty neurologist. The Board of neurology of JSN was started in 1975 as the third earliest of the Japanese Medical Associations. It takes at least 6 years of clinical training after graduating from the medical school to take the neurology Board examinations. By 2009, 4,000 members passed the Board examinations. In 2002, JSN published evidence-based “Treatment Guidelines 2002” of six diseases: Parkinson’s disease, stroke, chronic headache, dementia, and ALS. As to the international issues, JSN hosted the 12th World Congress of Neurology in 1981, and international activities markedly increased after that. The first informal meeting with JSN and Korean Neurological Association (KNA) was held at the 48th JSN Annual Meeting in Nagoya in May 2007. In May 2008, the KNA-JSN 1st Joint symposium was held at the 49th Annual Meeting of JSN in Yokohama on “International comparison of neurological disorders: focusing on spinocerebellar atrophies (SCA) and epilepsies.” In May 2009, KNA-JNS 2nd Joint Symposium was held at the 50th JSN Annual Meeting in Sendai, inviting a speaker from Taiwan Neurological Society, on the subject “History and Education of Neurology in Japan, Korea and Taiwan.” In this symposium, a strategy to make up the Northeast Asian Neurological Association was discussed.

Korea has special medical education including 2 years foundation, 2 years basic class, and 2 years clinical course. Korea Medical Association of Neurology was established in 1982 with five groups including stroke, epilepsy, movement disorders, neuromuscular diseases and infection diseases.

Though the first step was later than the European countries, they can catch up with them, even lead in some research now. The symptoms and morbidity are different from the other continent.

Ethical Principles

Since we became medical students we swore by the oath of medical student “life related, health

entrusted”. We were taught by our senior doctors, in every medical subdiscipline, the responsibilities and kind-heartedness, and the importance of excellent background knowledge. It says “Being a good doctor should be powerful in leechcraft like immortal, be kind like Buddha.” Neurology is also guided by the oath and law of the ancient Greek physician Hippocrates (born 460 BC) as for every other medical subdiscipline, but it may not be as popular as in the Western countries.

Key Values

Like the other disciplines the first key value of neurology is alleviating human sufferings, solving the problems of movement, feelings, perception, visual sense, hearing sense, mental impairments, personal dependence, and even death, which was caused by central nervous system and peripheral nervous system. The brain and spinal cord cannot regenerate, so the neurologists seek the way to prophylaxis the underlying diseases. Many neurological diseases have hereditary causes, and prenatal diagnosis can help these families, though the process and ethics are not consummate enough to practice. Till now neuroscience-based therapies and genetic treatments are not effective and widespread. Most neurological diseases have longer course to recover, so counseling and guidance of patients during and after an acute neurological disease and during the course of a chronic neurological disease for rehabilitation and spirit supporting are very important.

Conceptualization

Nature/World

Nature is conceptualized as every objective things against the subjective consciousness, including the *biological* and *biochemical* foundation of life on Earth. Nature entertains all dynamic processes in the environment. The world comprises the material, most importantly, the human being and artificial things, the countries. Our world has its own stable progressive politics, economics, and civilization.

Human Being

Biologically, the human being is considered as a kind of highly developed mammal with complex brain, which enables unique functions including many kinds of speech, abstract thinking, complicated emotions, strong spirit, rapid creativity, and the development of ethical categories such as morality, science, and art. Thus, humans are considered to be distinctive from the rest of the animal world in virtue of the unique capacities of the human brain.

Life and Death

In philosophy, life is conceptualized as the living things in our biological systems, ranging from bacteria, fungus, virus over plants and animals to humans. Since there is no unequivocal definition of life, the current understanding is descriptive, where life is characteristic of organisms that exhibit all or most of the following phenomena: homeostasis, organization, metabolism, growth, adaptation, response to stimuli, and reproduction. In the human body it is the operation of every different organ, including the nervous system. Death is considered the cessation of such physical functions. Medically “brain death” is an ethical challenge, which is illegal at this moment in Asia. So death is no activities physically including the brain and other organs.

Reality

Reality is considered true world, which is observed by the human beings with any kind of their senses. These different types of information are integrated by human’s brain, which is different from other animals.

Knowledge

Knowledge is understood to be the record of experiences, which can give human beings direction, can light their hope, and help them to make right decisions. Knowledge is a relatively complete, scientific, received standard, or research including every field. In neurology, knowledge was recognized by function of the cortex which depositing the history, experiences, idea and opinion on special things or events.

Truth

Truth is conceptualized as the reality underlying facts and rules, which is opposed to untrue, imagined, or guessed. The truth of neurology was least known compared to other disciplines.

Perception

Perception is the way you regard something and your beliefs about what it is like, and the way you notice things with your senses. In another way, it means the natural ability to understand or notice something quickly. The highest center of perception is our brain.

Time

Time is something that is measured in minutes, hours, years, etc., using clocks. It is a way of self-insight of humans. Time can also be a period of big events. It is a kind of parameter which is used to describe things moving or happening by human. A normal person has the ability to recognize the right time because of the cognition.

Consciousness

Consciousness is a kind of psycho-responsiveness of subjects to any physical stimulus like sound, light, pain, etc., from the outside world. It contains two parts, one is acceptance of the stimuli and the other is responding. The abnormality of consciousness was divided into two aspects: one is the level, and the other is the content. Changing in consciousness level can be graded ranging from coma, stupor, drowsiness to full *alertness*, which comprises crystal clear orientation concerning location, time, situation, person, and full mental capability. The typical change in consciousness content is delirium, which is usually caused by encephalopathy of different reasons.

Rationality/Reason

Rationality is behavior-based on clear, practical, or scientific reasons, which enables us to make decisions based on intelligent thinking rather than on emotion. Reason is the ability to make choice after thinking carefully based on facts. It is impaired in mental disorders, which is caused by injury of the cerebral cortex,

such as various kinds of dementia or neuropsychological abnormalities.

Mystery

Often mystery is considered to be something that is impossible to understand or explain or about which little is known. The mysterious things have the quality that cannot be explained in practical or scientific way, which is contradictory to modern medicine, including neurology. However, neurology has many unresolved issues. Science has its limitation in some way, but we do know to use our knowledge to resolve the mysteries.

Relevant Themes

A critical issue in neurology as regards “Science and Religion” is the notion of subjectivity. Especially in Chinese traditional medicine, there are orthodox rules, which are with personal experiences. But right now there is no pure Chinese traditional medicine at all. They try to identify the results in a scientific way too, so we call this a combination of TCM and Western medicine. Though there are many guidelines of treatment standards in neurologic diseases, they need more evidence-based proofs.

Neurology in Europe

Rüdiger J. Seitz

Department of Neurology, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany

Related Terms

[Neuroscience](#)

Description

Today, in Europe, Neurology is devoted to offering detailed diagnostic criteria and therapeutic

regimens for the clinical syndromes caused by diseases affecting the *brain, spinal cord, nerves, and skeletal muscles*. The term “Neurology” was coined by the German physician Moritz Heinrich Romberg (1795–1873). Throughout Europe, Neurology became a discipline in its own right in the middle of the twentieth century, being treated as a separate entity distinctive from *internal medicine* or *psychiatry*. This development started in the university hospitals, and was followed by the establishment of separate Departments of Neurology in most major community hospitals in the second half of the twentieth century.

Self-identification

Science

Neurology has self-identified, from its very beginning, as a natural science. It sees itself as a scientific endeavor with the aim to enhance the knowledge about the organization and function of the human ► [nervous system](#) as well as their disease-related abnormalities. The disease concepts and practices of clinical investigation were developed in the nineteenth century and substantiated by observations in *pathology* of the ► [nervous system](#) and physiological studies in experimental animals. The steadily accumulating knowledge of the clinical syndromes is considered as an objective basis for a specific curative or symptomatic therapy. Neurology counts itself among the so-called natural sciences because it applies the scientific methods of the natural sciences for clinical and basic research as well as for diagnostic procedures and therapeutic regimens. Progress in Neurology is reflected by the development of subdisciplines that initially were focused on the study of *neuroanatomy, neurophysiology, neuropathology, and pathophysiology*. This was pioneered for the broad range of human brain functions by Otfried Foerster (1873–1941). Being neurologist and neurosurgeon he supplemented his clinical observations with the cytoarchitectonic maps of the human brain as provided by Korbinian Brodmann (1868–1918) and with careful descriptions of

brain lesions and the effects of electrical stimulation of the cerebral cortex, which is the part of the brain that accommodates the bodies of the nerve cells. It affords brain function including motion, perception, language, emotion, consciousness, and reasoning during open brain surgery (Förster 1936). Subsequently, methods were developed which afforded to assess noninvasively abnormalities of functions of the human nervous tissue. This development started with Hans Berger (1873–1941) who invented the ► **electroencephalogram** and was followed by the development of the electromyography, electroneurography, and the evoked potentials. In the second half of the twentieth century the methodological repertoire expanded over *neurochemistry* and *neuroimmunology* to *neurosonology*, *neuroimaging*, and *molecular neurobiology* as the scientific basis of these methods became available. A prominent focus of scientific work in Neurology has been to elucidate the *pathophysiology* in neurological disorders. This involved also impairments in *cognition* (e.g., *aphasia*, *apraxia*, and *neglect*) that are considered topical to the discipline *Neuropsychology*. More recently, Neurology was equipped also with a broad spectrum of powerful therapeutic regimens resulting from the progress in *neuropharmacology*, *interventional neuroradiology*, and *neurosurgery*. Nevertheless, the pharmacochemical understanding of brain function is still in its infancies. This extends from the roles of the different neurotransmitters and their neuroreceptors for neurotransmission in the spinal cord to representations of brain function in the cerebral cortex and the subcortical brain structures including the interactions across these centers. In more recent times, multicenter randomized double-blinded studies have become increasingly important to establish evidence-based guidelines for treatment regimens.

The increase of knowledge in the different clinical and theoretical subdisciplines has fostered the emergence of a broad range of *neuroscience* specialties. This is reflected by national and international scientific organizations such as the European Neurological Society

(http://www.ensinfo.com/about_the_ens/index.html) and the European Federation of Neurological Societies (<http://www.efns.org/>). In addition, societies have been founded addressing specific brain diseases or research topics such as the European Stroke Council, European Epilepsy Academy, European Chapter of the International Federation of Clinical Neurophysiology. These organizations run their regular scientific meetings and the majority have their own scientific journals. These organizations show increasing numbers of members.

Characteristics

Neurology is distinctive among other specialties of Medicine in two aspects:

First, Neurology aims to establish a strong relationship between clinical deficit patterns and the topography of lesion location within the nervous system. This particular feature of Neurology guides the neurologist in assessing the clinical abnormalities in terms of the *pathophysiology* related to the affected functional systems, and in diagnosing underlying neurological disease (Fig. 1). Basic for Neurology is the notion that disease-induced lesions of the ► **nervous system** induce impairments of *motion*, *sensation*, *cognition*, and *emotion* that can be assessed objectively by the repertoire of clinical and diagnostic methods. Clinical observation has led to the conclusion that brain lesions typically do not disrupt these functions altogether or each of them completely, but rather selectively and to various degrees. This topographic organization is known to extend into the *cerebellum*, *brain stem*, *spinal cord*, the *peripheral nerves*, and *skeletal muscles* as well as sensory organs such as *eyes*, *ears*, and *nose*. In contrast, disorders in *internal medicine* typically affect the ► **nervous system** in a global manner, leading to *psychomotor slowing*, *apathy*, or even *coma*. Curative therapy is directed against the underlying disease, while modulatory therapy aims at interfering with *pathophysiology*.

Neurology in Europe, Fig. 1 Effects of a disease and of therapeutic approaches on the patient and his nervous system. The level of diagnosis is multifold

Second, Neurology grants that each organic abnormality can have adverse effects on the patient's psychological functions, and, conversely a patient's psychological state can affect his/her physical status (e.g., movement speed, movement range, and even the willingness to move at all). Accordingly, consideration of the psychopathological implications of a given neurological disease is essential to motivating the patient, both in terms of disease acceptance and in terms of willingness to pursue adequate therapy. Here, Neurology touches upon impairments in *emotion* and *personality* that are considered topical to the specialties in Medicine of *Psychiatry* and *Psychosomatic Medicine*. Accordingly, patient care in Neurology necessarily is interdisciplinary.

Relevance to Science and Religion

While clinical and basic *neuroscience* research has enjoyed a huge attraction across the world, most recently attempts have been made by *functional neuroimaging* to bridge the gap between human brain *physiology* and cognitive and emotional control of behavior, decision making, communication, and *metaphysical* experiences. This interdisciplinary discourse between the neurosciences and the humanities is still in its infancy.

Sources of Authority

The authorities in Neurology used to be scientifically interested physicians who were also instrumental in the establishment of dedicated academic institutions. In 1859 the National Hospital for Neurology and Neurosurgery was founded in London. At this institution Hughling John Jackson (1835–1911) who is considered the founder of modern Neurology was consulting physician. In Paris Jean-Martin Charcot (1825–1893) established a neurological clinic at the Salpêtrière hospital in 1882. In Germany the first Department of Neurology was established in Hamburg in 1896, which was advanced to the first chair of Neurology in 1919. It was held by Max Nonne (1861–1959). Since its infancies, Neurology has considered as authoritative foundational textbooks and handbooks on neurological diseases, as well as a series of human brain atlases. Historically, the first textbooks on neurological diseases were written by Charles Bell (1774–1842), Charles-Édouard Brown-Sequard (1817–1894), Jean-Marie Charcot (1825–1893), and R. Remak (1815–1865). In Germany Moritz Heinrich Romberg (1795–1873) published the “Lehrbuch der Nerven-Krankheiten” in 1851, followed by Wilhelm Erb (1840–1921) who published the first “Handbuch der Krankheiten des Nervensystems” in 1878. Starting in the 1960s, Pierre J. Vinken (born 1926) and George W. Bruyn (1928–2002) edited the “Handbook of Neurology,” which was published by Elsevier and today comprises more than 78 volumes (Vinken and Bruyn 1968). This handbook reflects the broad and diversified development of Neurology giving credit to the various subspecialties that have been established over the years. Of particular importance is the work of the neurosurgeon Jean Talairach (1911–2007) who developed a system for stereotactic localization of human brain structures, which was published in a series of human brain atlases. Beyond its use for stereotactic neurosurgery, it has become the reference system for localization brain activation in *functional neuroimaging*.

With the advent of the internet, electronic publishing and electronic libraries, original

publications in scientific journals have become increasingly important. Based on this rapidly expanding body of knowledge the neurological scientific organizations have established guidelines for *good clinical practice* and evidence-based guidelines which are constantly updated for therapeutic protocols of the major neurological diseases.

Ethical Principles

As for every medical subdiscipline, Neurology is guided by the oath and law of the ancient Greek physician *Hippocrates* (born 460 B.C.) who is considered the so-called father of medicine. This “Hippocratic Oath” has been supplemented by the rules of the Declaration of Helsinki of 1971.

Key Values

The key value of Neurology is alleviating human *sufferings*, understood as disorders of the ► [nervous system](#) and of the muscles which lead to physical and mental impairments, personal dependence, and even death. Toward that end, the neurologist employs and seeks to refine *neuroscience*-based therapies that are able to alleviate or even cure the underlying disease. A second key value in Neurology is that of counseling and guidance of patients during and after an acute neurological disease and during the course of a chronic neurological disease.

Conceptualization

Nature/World

Nature is conceptualized as the *biological* and *biochemical* foundation of life on our globe. Nature entertains all dynamic processes in the observable environment. The world comprises the material and the interspersed space of the universe.

Human Being

The human being is considered as a biological being equipped with a highly developed complex brain, which enables unique functions including speech, abstract thinking, creativity, and the development of ethical categories such as morality, science, and art. Thus, humans are considered to be distinctive from the rest of the animal world in virtue of the unique capacities of the human brain.

Life and Death

Life is conceptualized as the presence of physical functions in biological systems ranging from bacteria over plants and animals to humans. In the human body it includes functioning of the different organs, including the ► [nervous system](#). Death is considered the cessation of such physical functions. A special case, which has raised ethical challenges for Medicine, is that of so-called ► [brain death](#), which is observed in intensive care medicine. Here, non-brain bodily functions are maintained, but there is no evident brain activity.

Reality

Reality is considered the physical world around us that humans can observe with their senses.

Knowledge

Knowledge is understood to have an *objective* dimension, such that it is the *wisdom* that can be transferred in a verbal form from one person to the next, or has been written down in books or libraries. However, knowledge is also understood to have a *subjective* dimension, which is taken to be the amount of information a person can retrieve from *memory* voluntarily, or by being *cued*.

Truth

Truth is conceptualized as the supreme reality underlying facts and rules. Accordingly, truth is assumed to be absolute or universal which humans can grasp only partially.

Perception

Perception is the *conscious sensation* of the forces and influences the external physical

world exerts on living beings. Diseases of the human brain may disrupt or impair perception.

Time

Time is the fundamental category of ongoing change in the world. Humans can measure time *objectively* and perceive it owing to the changes observed in the surrounding environment. Human perception of time can be affected by the focus of *attention* or impaired by diseases of the brain.

Consciousness

Consciousness is the responsiveness of subjects to any physical stimulus in the outside world. It can be graded in different levels of *alertness* ranging from drowsiness to full *alertness*, which comprises crystal clear orientation concerning location, time, situation, personal biography, and full mental capability. Diseases can impair consciousness globally, or in differentiated fashions.

Rationality/Reason

Rationality is a foundation of accountable and *responsible* human behavior and of understanding reason as ultimate authority. It is impaired in mental diseases such as *dementia* or neuropsychological disorders.

Mystery

Often mystery is considered to be contradictory to modern medicine including Neurology. However, Neurology acknowledges in principle a place for mystery – i.e., that which is as yet unknown, and, thus, grants that contemporary knowledge may not have elucidated the entire physiology of human kind. In this view mystery is understood as potentially explainable after accumulation of adequate scientific knowledge.

Relevant Themes

A critical issue in Neurology as regards “Science and Religion” is the notion of *subjectivity*. Subjectivity includes the individual perception of the

outside world and the own body as well as the individual reasoning and valencing of personal experiences, short-lived thoughts, and long-standing *ethical categories*. This pertains to the gap between a science-based medicine and the empathic caring for a physically dependent and/or mentally deprived patient.

Neuromodulation

Wilhelm E. Eisner

Department of Neurosurgery, Medical University
Innsbruck, Universitäts-Klinik für
Neurochirurgie Innsbruck, Innsbruck, Austria

Treatment of cerebral disorders like movement disorders, therapy-resistant epilepsy, severe central pain syndromes, severe therapy-resistant psychiatric disorders by deep brain stimulation or spinal cord stimulation, vagal nerve stimulation, and peripheral nerve stimulation.

A neuromodulation system consists of an electrode and a stimulator, sometimes it is an extension cable interconnected. The systems are completely implanted. That means the electrode, the extension cable, and the impulse generator are completely covered by skin or human tissue preventing bacterial or fungal infection of the system and the human tissue. Electrical stimulation is able to mimic neuronal impulses to the brain and is further able to modulate neuronal transmission in respect of augmentation or inhibition. High frequency stimulation (>100 Hz) acts inhibitive in contrast to lower frequency stimulation. Neuromodulation is reversible. That means interruption of current application restores the preoperative neurological state. The therapy can be modulated in frequency, intensity, and impulse widths.

Related Terms

[Dendrite](#)

The principle component of the nervous system responsible for processing and transmitting information to other cells via biochemical signals. The human brain contains roughly 100 billion neurons. Neurons contain a nucleus holding genetic information and are surrounded by a protecting membrane. The task of the membrane is to send information to other cells. The neuron's basic parts are the cell body, the axon and the dendrites, specialized structures to transmit and receive information. The dendrites receive the information passed down to the cell body and on to the axon. The dendrites and the axon are connected

via synapses. The information, once it has arrived at the axon, travels down the length of the axon as an electrical signal (i.e., action potential) and when this electrical signal has reached the end of the axon the information is transmitted across the synaptic gap to the dendrites. Bridging the gap between the neurons may be done instantaneously or by way of chemical messengers called neurotransmitters. A neurotransmitter is a chemical substance which is produced by the nervous system and conveys information between nerve cells. There are different neurotransmitters such as dopamine, serotonin, noradrenaline, and acetylcholine. Acetylcholine also transmits information between the peripheral nerves and the skeletal muscles.

Related Terms

[Pathology of the nervous system](#)

Description

Neuropathology is the discipline that studies structural changes of the nervous system in neurological diseases. Originally this comprised only gross and microscopical examination of nervous tissues, in particular of the brain, but also of spinal cord, peripheral nerves, and skeletal muscle. However, more recently additional methodology applied in neuropathology to studies of diseased nervous tissues includes biochemistry and molecular biology as well. Neuropathology gives diagnoses on tissue

obtained by biopsy or autopsy and is essential to confirm the validity of clinical diagnostic criteria and efficacy of therapeutic measures. As an example, operated brain tumors are classified by neuropathologists in distinct diagnostic types as an essential prerequisite for further prognostic and therapeutic considerations (Louis et al. 2007). In many parts of Europe, neuropathology developed from clinical neurology or psychiatry by studying the “Hirnpathologie” (brain pathology) of patients who had died in the same department, in the way Alzheimer studied the brain of Auguste D. as model of the disease that now carries his name. In the Anglo-American tradition, however, neuropathology has more roots in general pathology, when pathologists felt the need for detailed specialization.

Self-identification

Science

Neuropathology self-identifies as a medical discipline that is deeply rooted in natural or life sciences. It aims to improve human health by better understanding of the nervous system during disease. So, on one hand, it is a medical service that relies on learning, observation, and experience, while on the other hand, it fully qualifies as scientific discipline that aims to increase scientific knowledge about diseases of the nervous system by hypothesis-driven experimental research.

Characteristics

Neuropathology excels among other disciplines of medicine by its approach to get to the roots of neurological disorders. Indeed, neuropathology is in the very center of research on diseases of the nervous system, at the interface between basic science and clinical neurosciences (European Confederation of Neuropathological Societies; International Society of Neuropathology). While

in many cases clinical neurology and psychiatry are limited by less-than-perfect diagnostic methodologies, as direct access to nervous tissues is limited in the living patient, neuropathology has the advantage to directly study diseased tissue in situ that is obtained by biopsy (e.g., neurosurgical (Louis et al. 2007; Love et al. 2008; McLendon and Bigner 2006), nerve or muscle (Karpati 2002), rarely brain biopsies, or cytological study of the cerebrospinal fluid) or autopsy (Dickson and Weller 2011; Kalimo 2005; Love et al. 2008). This greatly contributes to the excitement of neuropathology: to be able to check what goes on in brain tissue itself, whereas other clinical methods have to rely on small surrogate “windows” to the brain, e.g., by studying the cerebrospinal fluid.

Relevance to Science and Religion

Neuropathology contributes to our basic understanding of disturbed cognitive, emotional, and behavioral functions. As both science and religion are based on such deeply human functions, neuropathology might be considered to link both areas, in particular in disease-related states. However, there is no direct interest in, and connection to, religion by neuropathology.

Sources of Authority

Neuropathology has been the basis of many historical descriptions of diseases of the nervous system. Like Alzheimer, many of the famous figures of neurology and psychiatry made salient observations by studying tissue alterations in diseases that in part are linked to their names. Practically all diagnostic classification schemes have a neuropathological basis, in particular in diseases with prominent structural changes such as tumors (Louis et al. 2007; Love et al. 2008; McLendon and Bigner 2006) or neurodegenerative disorders (Dickson and Weller 2011; Love et al. 2008).

Ethical Principles

Like all other medical disciplines, neuropathology has to observe all ethical principles that guide the medical profession, ranging from the Hippocratic Oath to the Declaration of Helsinki.

Key Values

The key value of neuropathology is that it provides definite neurological diagnoses and distinct clues on the pathogenesis of nervous tissue lesions. Many clinical diagnostic methods have to await validation by comparison with neuropathological diagnoses as golden standard.

Conceptualization

Nature/World

Nature is conceptualized within the universe of life sciences to which neuropathology belongs. The world is perceived by humans by their brain that is, among other functions, the target of neuropathological assessment during disease. Thus, what we realize is conceptualized in all its qualities as perception of the outside world by the inner world of the brain.

Human Being

The human being may be defined by the abilities of the human brain. Without the human brain, all that makes human beings human beings is lost.

Life and Death

For neuropathology and other natural sciences, life is conceptualized as a universe of physiological processes that characterize distinct biological systems, from single-cell organisms to complex individuals who have the brain as their most complex living organ. Death constitutes the end of these processes and thus may occur at several levels, at cell, organ, or individual level.

Reality

For human beings, reality seems to represent what of the outside world they perceive with their senses.

Knowledge

Knowledge is gain of understanding and reasoning, by learning and experience, or by experimental scientific research. There is nothing specific that neuropathology, as medical and scientific discipline, can provide to the definition of this term.

Truth

There is nothing specific that neuropathology, as medical and scientific discipline, can provide to the definition of this term.

Perception

There is nothing specific that neuropathology, as medical and scientific discipline, can provide to the definition of perception that can be decisively impaired by diseases of the brain that are the study target of neuropathology.

Time

There is nothing specific that neuropathology, as medical and scientific discipline, can provide to the definition of this term. However, the perception of time can be decisively impaired by diseases of the brain that are the study target of neuropathology.

Consciousness

Consciousness is the cognitive condition in which you are aware of yourself as well as of the environment in which you are situated. Consciousness can be decisively impaired by diseases of the brain that are the study target of neuropathology.

Rationality/Reason

Rationality seems to be a quality of a human being, or of its products, of having a sound, logic, and balanced approach to problems. There is nothing specific that neuropathology, as medical and scientific discipline, can provide to the definition of this term.

Mystery

Mystery defies common understanding and experience. It cannot be explained by common knowledge. Thus, mystery is a challenge to a scientific approach to the world that we live in. Neuropathology, as a scientific discipline, may contribute to solve some mysteries that need to be resolved in the area of diseases of the nervous system.

Relevant Themes

As there is no direct interest of neuropathology in religion, it does not have additional and critical issues in this area.

Neurophysiology

Heiko J. Luhmann

Department of Physiology, Institute of Physiology and Pathophysiology, University Medical Center of the Johannes Gutenberg University of Mainz, Mainz, Germany

Description

Neurophysiology is a subdiscipline of the scientific disciplines *physiology* and *neurosciences*. Neurophysiology is devoted to the functional analysis of the *peripheral nervous system* (PNS) and the *central nervous system* (CNS) applying a variety of experimental and clinical methods. The neuronal structures of interest range from subcellular components (e.g., single voltage-dependent channels or neurotransmitter-gated receptors) to whole organisms. Since the nervous system operates via digital and analog electrical signals (action potentials and synaptic potentials, respectively), classical as well as modern neurophysiological methods generally measure the electrical activity (electrophysiology). Nowadays, neurophysiological techniques are often combined with methods of other scientific disciplines, such as *anatomy*, *genetics*, *molecular biology*, *computational neurosciences*, or *psychology*.

Self-identification

By definition, Neurophysiology is the science devoted to the physiological or functional analysis of the nervous system. Neurophysiology

belongs to the so-called natural or life sciences. Neurophysiology uses physical and chemical methods to study the function and dysfunction (as in *neurology*) of the nervous system or to manipulate the neuronal function (e.g., via electrical stimulation electrodes).

Characteristics

Neurophysiology is partly devoted to the analysis of higher nervous functions, e.g., learning, memory, consciousness. It is distinctive among other specialties of physiological and life sciences that Neurophysiology is studying the molecular and cellular mechanisms underlying these higher nervous functions.

Relevance to Science and Religion

Since Neurophysiology studies the functional states of the nervous system, including the human brain, it is most relevant in the scholarly area called “Science” and to society.

► **Electroencephalogram (EEG)** recordings of the neuronal activity in the human brain performed by Benjamin Libet (1916–2007) have demonstrated that unconscious neuronal processes precede volitional acts by approximately 0.5 s, questioning the existence of a *free will*. These experiments may indicate that consciousness is a side effect of basic neuronal function and an epiphenomenon of brain states. Although Libet’s experiments and conclusions are controversially discussed, they may have a strong impact on society.

Sources of Authority

The role of electrical activity in body function was first described in 1783 by the Italian physician and physicist Luigi Galvani (1737–1798) when he discovered by chance that frog leg muscles contract upon electrical stimulation. Later, the German physician and physiologist Emil du

Bois-Reymond (1818–1896) discovered the nerve action potential. In 1924, the German physician Hans Berger (1873–1941) performed the first EEG recordings by connecting silver foil electrodes on a patients head with a galvanometer. The English physiologists Alan Lloyd Hodgkin (1914–1998) and Andrew Fielding Huxley (born 1917) received in 1963 the Nobel Prize in Physiology or Medicine for their work on the basis of the nerve action potential, which they performed on the so-called giant axon of the squid. In 1991 the German physicist Erwin Neher (born 1944) and the German physiologist Bert Sakmann (born 1942) received the Nobel Prize in Physiology or Medicine for their discoveries concerning the function of single ion channels in cell membranes and for the development of the so-called patch-clamp technique.

The Canadian psychologist Donald O. Hebb (1904–1985) published in 1949 the famous book “The Organization of Behavior” in which he defined a cellular basis of learning, later termed Hebb’s Law (“Neurons that fire together, wire together”): “When an axon of cell A is near enough to excite cell B and repeatedly or persistently takes part in firing it, some growth process or metabolic change takes place in one or both cells such that A’s efficiency, as one of the cells firing B, is increased.”

The function of a sensory system in the mammalian brain was studied in great detail by David H. Hubel (born 1926) and Torsten N. Wiesel (born 1924) by performing electrophysiological recordings from single nerve cells in the visual system of the cat. For their discoveries concerning information processing and developmental *plasticity* in the visual system, both received the 1981 Nobel Prize in Physiology or Medicine.

Ethical Principles

In contrast to in vitro neurophysiological studies on isolated brain tissue or single nerve cells in culture, in vivo neurophysiological experiments on anesthetized and non-anesthetized animals

and humans often require the permission of a local ethical committee. These experiments are performed according to national and international laws on the use of animals and humans in research. Clinical investigations using neurophysiological techniques are performed according to the rules of the *Declaration of Helsinki*.

Key Values

The key value of Neurophysiology lies in the understanding of brain function and dysfunction, from subcellular mechanisms to the behavior of the whole organism or human being. Neurophysiological methods are used to identify and to define the states of consciousness and unconsciousness (as during sleep with different functional states of consciousness associated with distinct brain rhythms detectable with the EEG).

Conceptualization

Nature/World

Nature is defined as the physical, chemical, and biological components and processes of living and nonliving parts ranging from the subatomic to the galactic scale.

Human Being

A human being is defined as a bipedal primate of the species *Homo sapiens* with a highly organized brain allowing complex neural functions, such as language, abstract thinking, introspection, science, and art. This mental capability allows human beings to develop concepts of ethics, morality, and religion.

Life and Death

Life is defined as the process of *self-organization* and self-production of an organism which requires energy. Living beings may interact with their environment by the use of sensory organs and their nervous system. In clinical Medicine, an isoelectric (flat-line) EEG is used as one criterion to diagnose brain death in humans.

Reality

Reality is defined as the conscious perception and neuronal processing of sensory information from the external world and from the internal body.

Knowledge

Knowledge is the genetically determined and individually acquired information about the world and oneself stored in neuronal networks of the brain.

Truth

Truth is a proven or verified fact, principle, or information.

Perception

Perception is defined as the transduction of a physical or chemical stimulus from the external world or internal body via a sensory system, its neuronal processing within the brain, and its conscious perception.

Time

Time is the subjective perception of the interval between two events.

Consciousness

Consciousness is a distinct functional state of the brain which enables neuronal processing of information from the external world and internal body or which is generated by imagination and meditation.

Rationality

Rationality is a measure of consistency in individual thinking and action.

Mystery

A mystery is something not understood or beyond current human comprehension.

Relevant Themes

The question on the mechanisms underlying the processing of neuronal information in the brain, the so-called neuronal code, is currently of central interest in Neurophysiology and in *Neurosciences*.

[Brain and behavior](#); [Cognitive](#); [Religious experiences](#)

Description

In contemporary terminology, neuropsychology is the scientific study of the relationship between

the brain and behavioral functions. Central to its purview is the attempt to first understand and then utilize the way brain activity and structure interrelate with psychological functions, such as mental illness, mood, perception, and cognition. As this suggests, there are loosely two foci or branches of neuropsychology. The first, which some call cognitive or experimental neuropsychology, focuses on understanding how human behavior and mental operations arise from brain activity, such as the way patterns of behavioral deficits can be explained in terms of disruptions to damaged neural components. It tries to understand how the functioning of the brain translates into the everyday behavior of the person, as well as the way changes in thought and behavior relate to the structure and function of the brain.

The second emphasis, perhaps synthetically termed clinical neuropsychology, is concerned with the assessment, management, and rehabilitation of neurological disease and injury. It is this emphasis that makes neuropsychology an applied science because it is concerned with assessing and managing the behavioral expression of the brain dysfunction identified by cognitive neuropsychologists. This includes understanding how the deficits associated with neurological conditions are demonstrated, such as strokes, head injuries, and various forms of dementia. To do this, neuropsychological investigations are used to assess a person's cognitive skills and to identify impairments that result from brain trauma and diseases that affect the brain. Among the tools that are employed are standardized cognitive and emotional testing, electroencephalography, neuroimaging (CT, MRI, fMRI, SPECT, PET), the intracarotid sodium amobarbital procedure (Wada test), and transcranial magnetic stimulation. Of these, standardized cognitive and emotional measures are the most commonly used due to their flexibility, price, and facility for tapping into various cognitive functions, such as memory and language, that correspond to general regions and functions of the brain.

Over the past several years, there have been some significant advancements in the field of neuropsychology. Although single-case studies

continue to provide much of our knowledge about the relationship between brain and behavior, there is a growing interest in group studies, likely related to their greater generalizability. One of the by-products of this has been a loosening of attention on focal brain regions and a greater appreciation for the role of neural networks and systems in human behavior, emotion, and neurological disorders. This has been aided by multiple technological advances. Standard measures of neuropsychological assessment are not only improving in their psychometric properties, including being normed and standardized across age and cultural groups, but they are also becoming increasingly paired with new technologies that allow for observing and rehabilitating neurological processes. These include dichotic listening, lateral visual half-field viewing, staining methods to map connections, and functional imaging to capture a dynamic, three-dimensional (3D) representation of brain activity during specific behaviors in both normal and brain-injured subjects. In a similar vein, virtual reality (VR) is being increasingly used to provide multisensory 3D stimulus environments, advanced methods for recording behavioral responses, and ecologically valid simulations that afford a richer understanding of the brain and more immediate feedback during neurosurgery and rehabilitation. Even the emergence of VR approaches reflects neuropsychology's growing scope, addressing not only diagnosis and assessment but also treatment planning and intervention.

Embracing these advancements, some of the fastest growing areas of neuropsychology are in the domains of forensics, sports, terrorism and law enforcement, and gerontology. Neuropsychologists are being increasingly asked to present and evaluate assessment results in the courtroom, as well as to determine the emotional and behavioral sequelae of brain damage in personal injury and criminal cases. This includes complex evaluations of malingering potential, assessment of competency and responsibility, and the capacity for rehabilitation. The sports arena is relying on neuropsychology to understand sports-related injuries, such as concussions, that have short- and long-term consequences. In our growing

age of terrorism awareness, neuropsychology has contributed to the dialogue about the cognitive operations in terrorism, how the brain reacts to elevated anxiety among law-enforcement officials, and how to facilitate optimal decision-making. Moreover, neuropsychology is responding to the advancing age of the general population. This includes not only assessing, diagnosing, and offering treatment recommendations for those with age-related conditions like dementia or Parkinson's disease but also diagnosing earlier manifestations of these conditions that are not readily recognizable by neuroimaging. Similar to the positive psychology movement, this has contributed to the field's shift away from solely focusing on overt injury toward understanding the features of normal behavior and brain function. In doing so, neuropsychology is adding to our understanding about ways to facilitate optimal quality of life and the capacity to succeed in the present environment.

Self-Identification

Science

Neuropsychology self-identifies as a natural and biobehavioral science. It has deep roots in, and a strong commitment to, the scientific method and the principles of objectivity and replication. Using objective examination, it attempts to describe *what* happens in brain-behavior relationships, predict *when* it happens, use systematic control to understand what *causes* it to happen, and offer explanations for *why* it happens. Most of the research in the field is based on hypotheses that can be rejected and designs that maintain experimental control to exclude unwanted variables. When possible, neuropsychologists attempt to include a comparison sample to observe derivations from the sample, although some of their studies are necessarily quasi-experimental because they cannot ethically or practically manipulate some independent variables. It would be unethical, for example, to give parietal lesions to half of the participants in a study. This does limit the generalizability of some findings, but

neuropsychologists attempt to replicate their results to ensure the accuracy of their observations and findings. Neuropsychology is therefore a dynamic and empirical enterprise, building on and refining older observations while making its knowledge and practices open to revision.

Characteristics

Neuropsychology draws on information from several disciplines, including anatomy, biology, pharmacology, physiology, neurosurgery, psychometrics, and philosophy, with the central goal of developing a science of human behavior based on the function of the human brain. Technically, it is a subspecialty or subdiscipline of psychology, which is the study of the mind and behavior, but neuropsychology narrows psychology's scope by examining how complex properties of the brain allow behavior to occur. Like psychology, it describes, explains, and predicts behavior, but it uniquely seeks to understand how this behavior is related to the activity of the brain.

Similar to clinical psychologists, the training of neuropsychologists often includes methods of psychotherapy, counseling, and assessment. They can also provide therapeutic services to patients in need of education and emotional support concerning their neurological injuries or illness. Where clinical neuropsychologists often differ is that they also have extensive knowledge of the brain, including an understanding of neuroanatomy, psychopharmacology, the use of neuropsychological tests to assess cognitive deficits, and the management, treatment, and rehabilitation of brain impairment. In short, neuropsychology is a unique niche of psychology that studies how changes in thought, behavior, and mood relate to the brain's structure and activity.

Relevance to Science and Religion

Unlike the long history between religion and neuropsychology's parent discipline (i.e.,

psychology), the field of neuropsychology is in its infancy in contributing to the dialogue between science and religion. However, the relevancy of neuropsychology to the science and religion discussion is evident even in its philosophical assumptions about the mind-body problem. Deeply embedded in the philosophy of neuropsychology is an abjuration of Cartesian dualism. Taken to the extreme, this could result in the materialization of religion, demoting it to one of many human behaviors or experiences that can be reduced to specific brain processes. Some neuropsychologists rescue religion from this reductionism by adopting a nonreductive form of physicalism, arguing that the human qualities that are distinct to religion are among other higher-order capacities, like creativity and relatedness, that are emergent properties, larger than the sum of the material parts of the brain. Even with this nonreductive physicalism, the findings of neuropsychology introduce significant challenges to a dualistic view of persons and invite greater discussion about the embodiment of spirituality and religion.

Some of this discussion about the nature of personhood and the relationship between religion and brain was given a fillip when the notion of bimodal consciousness, first introduced by ► [split-brain research](#) on the independent functions of the left and right hemispheres, was proposed as a basis for elaborating on different patterns of belief. This generated greater attention to the neural correlates of belief and disbelief, although it remains unanswered whether a belief in a truth that can be verified is different than a belief in something that is unverifiable.

Following this research has been significant interest in the unavoidable relationship between neurological activity and religious experiences. Something clearly happens in the brain during meditation. Similarly, divine intervention insufficiently explains the increase in religious experiences among those with temporal lobe epilepsy. Unable to ignore these relationships, neuropsychologists have been giving greater attention to both normal religious processes

and those that occur in the context of overt neural pathology.

The latter probably emerged first, as seen in the religious experiences of those with epilepsy, schizophrenia, and other brain diseases. For some time, it has been known that individuals can experience chemically induced religious experiences under the influence of LSD. Long-standing research has revealed that those with temporal lobe epilepsy have a greater propensity than the general population for developing religious experiences, including religious hallucinations and feelings of unity with the external world. Mania and depression can be associated with mood-congruent delusions. It is also not uncommon for the positive symptoms of schizophrenia, particularly hallucinations and delusions, to be infused with religious content and meaning. Despite the religious or spiritual nature of these symptoms, there is little doubt that they are mediated by neuropathological substrates, most likely greater frontal and left temporal activation.

Similarly, there is a clear neurological foundation to the greater levels of religiousness and greater meaning given to spirituality by those with frontotemporal dementia (FTD) (Rosso et al. 2001). This increased religiousness and preoccupation with religious ideas may be one of many behavioral excesses that occur in FTD, alongside hyperorality and hypersexuality. This may be related to the deterioration and atrophy of the orbitofrontal regions that occur in FTD, which leads to a loss of inhibition and a spontaneous release of compulsive and stereotyped behavior, such as hyperreligiousness. Another possibility is that increased religiousness is a by-product of the altered ability to infer one's own and others' mental states, which seems especially related to the degeneration of the ventromedial prefrontal cortex. Many of those with FTD undergo significant changes in their concept of self, including food preferences, dress styles, and even religious ideology. Some of these changes can also be traced to abnormalities in the right frontal lobe, suggesting that normal functioning of the right frontal lobe is necessary

for the maintenance of key aspects of self, including religiousness. This highlights the potentially challenging reality that religion is affected by neurological changes and activity.

It would be easy to look at this research and simply conclude that religion is a secondary by-product to pathological processes or, more concisely, that mysticism is not that far from madness. However, the emergence of a field called "neurotheology," which attempts to identify neural substrates putatively mediating spiritual experiences, has helped shift attention away from pathological manifestations of religion to specific areas of the brain activated during *normal* religious experiences, such as prayer or meditation. For example, a substantial amount of research has implicated a frontal-parietal circuit underlying normal spiritual and religious experiences. When Carmelite nuns were asked to "remember and relive the most intense mystical experience ever felt in their lives," the brain areas that were activated were medial orbital, medial prefrontal, anterior cingulate, and parietal cortices (Beauregard and Paquette 2006). During religious meditation, Franciscan nuns and Tibetan monks showed increased blood flow in prefrontal, inferior frontal, and inferior parietal lobes, commensurate with a marked decrease in the activity of the posterior superior parietal lobe (Newberg et al. 2003; Newberg et al. 2001). Moreover, out-of-body and near-death experiences seem to be related to hippocampal and limbic hyperactivation. Clearly, there are neural substrates to even normal religious experience.

This research raises important questions that neuropsychology and religion will eventually have to address. Should this neurological basis be taken as evidence that our brains are wired for dialogue with the divine? Some have brazenly taken these findings as revelation for a God spot in the brain. If we make this conclusion, what do we do with the finding that religious experience is often the result of neural hyperactivity or an unnatural release of inhibition, rather than a normal manifestation of brain activity at rest? An alternative option might be to co-opt these

findings to argue that all spiritual or religious experience is merely an artifact of neural activity, without any corresponding connection or meaning to some nonphysical entity. Those adopting this approach could argue, for example, that revelations occur on mountains primarily due to the effects of chronic altitude hypoxia on the prefrontal cortex and temporoparietal junction. This conclusion seems unwarranted, though, because, to date, the only research in this area is correlational in nature, showing an *association* between certain experiences and certain brain activities, but not that religious experience is an *effect* of neurological processes. Although there are no certified answers at this point, it is clear that neuropsychology is showing itself to be a tool to aid in understanding theology, religion, and spirituality.

Sources of Authority

The primary source of authority for the field of neuropsychology is scientific research. Our knowledge of the brain and its influence on human behavior is constantly being furthered, challenged, and refined by research studies. This includes empirically derived data from neuropsychological testing, brain imaging studies, and cognitive science, to name a few. Many neuropsychologists place the primary focus on quantitative data, although some notable figures in the field also endorse an approach that incorporates qualitative data (e.g., the Boston process approach).

If the primary source of authority is scientific research, then the principal method for accessing this source is journal articles, particularly recent ones. Although journal articles are given greater authoritative value, books and book chapters can also be helpful resources for reviewing the current knowledge in a particular area of research. Unique weight is given to those that are grounded in scientific or empirical methodology rather than theory alone. Moreover, influential neuropsychologists who have written significant works, such as Alexander Luria (Luria 1976), Muriel Lezak (Lezak et al. 2004), and Edith Kaplan (Kaplan 1988), serve as sources of authority by

the nature of their seminal writings and because their important conclusions are consistently tested and refined.

Ethical Principles

Neuropsychology is guided by the ethical guidelines of the American Psychological Association (American Psychological Association 2002) and the American Medical Association, as well as supplementary publications that pertain to ethical standards for this field. These include such principles as respect for human dignity, professionalism, integrity, and beneficence rather than maleficence toward clients. Competency is a key principle, which includes attaining proper education and training, as well as appreciating the role of cultural context in research and clinical work. It is important for neuropsychologists to avoid dual or multiple relationships that may compromise professional boundaries and misuse the power differential with clients or research participants. Neuropsychologists submit their research to Institutional Review Boards, seek to protect patients' and participants' privacy and confidentiality, and ensure that informed consent is achieved. They also strive to minimize risks to mental or physical health, which includes using measures that are psychometrically sound and that have culturally sensitive norms. To ensure adherence to these ethical principles, neuropsychologists are typically licensed by the Board of Psychology in their respective states and held to the standards of the American Psychological Association's Code of Ethics.

Considering the rapid growth and technological advancement in neuropsychology, a new field has emerged called "neuroethics." This field deals with ethically challenging questions and dilemmas, such as the effects of psychotropic medications on the mind, the determination of mental capacity and informed consent, the rights of the individual versus the interest of society, and issues involving personal identity and sources of meaning. This field will likely continue to guide the development and refinement of the ethical principles in neuropsychology.

Key Values

In addition to subscribing to the highest level of ethical principles, neuropsychology also places a high premium on the values of curiosity, scientific inquiry and rigor, and materialism. To be a neuropsychologist first and foremost requires that one is curious – curious about behavior, emotions, and the interaction between brain activity and behavioral expression. It is this inquisitiveness that cultivates a high level of openness and creativity on the behalf of the neuropsychologist, ideally letting the patient or research findings speak on their own terms. In a sense, neuropsychologists prefer to be the *object* that the *subject* of the patient or research findings impresses itself upon.

This inquisitiveness is given structure and objectivity by the importance placed on scientific inquiry and methodology. Trained in clinical psychology programs, most neuropsychologists aspire to the principles of objectivity, controlled observation, experimentation, confirmation of predictions, statistical analysis, and replication. Experimental control and falsifiability are highly cherished, as well as honesty in reporting and healthy skepticism in both interpreting and writing. Such a reliance on scientific methodology as the primary method of epistemology may eclipse other methods of knowing, such as insight or experience, but those in this field are often willing to forego this knowledge to avoid false-positive conclusions and to secure the greater control and caution that are garnered by scientific principles.

Most of neuropsychology is also infused with a high level of ► [materialism](#). Even in its early forms, neuropsychology emerged out of a reaction to nonmaterial explanations of human behavior and emotion, be they religious or environmental. Deep within the core of this field is an attempt to seek knowledge about the material world of the brain and to localize brain disease and psychiatric problems within the physiology, structure, and networks of neural functioning. Consequently, most research questions and findings are viewed through the lens of materialism.

Conceptualization

Nature/World

Nature/world are primarily conceptualized as being naturalistic and physicalistic. In other words, they consist of material things that can be understood using the scientific method. From a neuropsychological perspective, this includes internal neural activity, such as brain-behavior relationships and emotional and cognitive processes, as well as the external physical environment with which this neural activity interacts.

Human Being

Most neuropsychologists conceive of the human being as a material and physical entity. As previously mentioned, when confronted with the mind-body problem, neuropsychology predominantly champions materialism and a bottom-up view of human behavior and mental activity. In other words, the aspects and characteristics that distinguish someone as human are largely neurological and the sum of the parts. There may be emergent properties that cannot be reduced to individual neurological elements, such as morality and the capacity for relationships, but many neuropsychologists struggle with this view because it introduces an unknown and unobservable element that is contradictory to their values of empirical testing and falsifiability.

Although all parts of the brain likely contribute to the essence of humanness, particular attention is often given to the frontal lobes and the prefrontal cortex. This is because the frontal lobes are the last region of the brain to develop, both from an evolutionary and ontogenetic perspective. They are the final and most advanced region of the brain, which most likely evolved to guide organisms toward selecting the behaviors that confer the best chances of survival. It is this region that is intimately involved in personality, emotion, information processing, language, and executive functions (e.g., abstraction, planning, inhibition), all of which constitute the unique cognitive and neurological features that distinguish us from nonhumans. Inherent in this is an evolutionary perspective, implying that humans have evolved from nonhuman species and that

their basic neurophysiology and neuroanatomy give rise to those features that distinguish humanity.

Life and Death

Put simply, life is the presence of neurological and cardiovascular activity, born of evolutionary processes. Death, in contrast, occurs in two forms. On a microlevel, there can be neuronal and synaptic death that occurs during normal cognitive aging and/or brain injury. The macroform of death is the complete cessation of these neurological and cardiovascular processes.

Reality

Reality corresponds to the objective state of the external environment. Humans gain information about reality primarily via sensory experience and develop cortical maps, or internal representations, of reality. Distortions in a person's understanding of reality can occur when there are disruptions in neural processing, as commonly manifested in the delusions of those with schizophrenia.

Knowledge

Knowledge is the accrual or combination of both learned and innate information. The acquisition of knowledge involves long-term potentiation and the strengthening of synaptic connections. Once acquired, knowledge is retrieved from different areas of the brain, primarily in the temporal-parietal-occipital regions, depending on the category or type of knowledge. Knowledge is then expressed through language or demonstrated by motor behaviors.

Knowledge also has a complex and interwoven relationship with intelligence. Many neuropsychologists conceptualize intelligence as the way one applies knowledge to a variety of scenarios and problems in life. However, it is also recognized that there are different forms of intelligence, ranging from fluid and crystallized intelligences to a wide range of abilities and skills, including musical, bodily kinesthetic, linguistic, and interpersonal intelligences. Therefore, knowledge and intelligence are not interchangeable concepts; rather, intelligence is the application of all sorts of knowledge to the vicissitudes of life.

Truth

Absolute truth cannot be fully known or discerned. Using scientific findings about brain-behavior relationships, it is possible to only gain successively closer approximations to truth. Neuropsychologists deal with hypotheses, theories, and data, which must be verified repeatedly and statistically with a large, representative sample. Even when findings or ideas meet these criteria, they are always regarded with a healthy dose of suspicion based on the possibility of subsequent studies supporting inconsistent findings. As a result, the closest we can approximate truth is through the aggregation of repeatedly verified scientific findings.

For the individual, truth is often relative and defined through attributional processes that are linked to specific neurological pathways. To a certain extent, truth is the result of a neurally based schema or interpretation system through which events and experiences are filtered. As a case in point, some individuals with dysregulated brain functioning (e.g., Korsakoff's syndrome) will confabulate or generate false narratives that they hold as truth. Others, like those with Parkinson's disease, may have visual hallucinations accompanied by difficulty differentiating between real events and internal representation of events.

Perception

Neuropsychology recognizes that sensation and perception are inextricably intertwined. In their simplest form, sensation refers to the neural detection of stimuli, whereas perception is the interpretation of those stimuli. Perception helps to make conceptual sense of what the senses have detected. It can happen in response to external stimuli, such as a traffic signal, or internal stimuli, such as a rapid heartbeat. In both of these cases, the stimuli are first detected and then interpreted. A red traffic light might be interpreted as an indication to brake one's car, just as a rapid heartbeat might indicate nervousness or physical exertion during a workout. Perception refers to this interpretational process, which involves many different streams of processes in the brain, depending on the nature of the stimulus.

Distortion of these normal perceptual processes can be caused by multiple factors, such as hallucinogenic drugs or the chemical imbalances in the brain that accompany some neurological disorders, such as schizophrenia.

Time

Neuropsychology's concern with the subject of time centers on the internal perception and representation of time intervals. Time perception involves many different cortical systems working in parallel, including sensory-perceptive and semantic processing governed by an integrated web of neural systems involving the basal ganglia, cerebellum, and hippocampus. Some mechanisms are specialized to detect and estimate shorter time intervals, while others are specialized for longer time durations. Memory is also involved in the detection and recall of the passing of time; working memory is necessary for shorter intervals, whereas episodic and long-term memories are required for longer intervals. Moreover, the accuracy of time discrimination may depend on neurological functioning, as reflected in the differences in time accuracy between normal and psychiatric populations.

Consciousness

Consciousness refers to a general alertness or awareness, which emerges from the intersection of various cognitive functions, including arousal, perception, attention, and working memory. Several automatic behaviors occur below the threshold of consciousness, such as breathing and eye movement, since there is no awareness or voluntary effort required to control these processes. Attention is therefore necessary in order for a stimulus to break into consciousness. This may be why greater attention and a higher level of consciousness are elicited in the presence of novel and/or unexpected stimuli. Among the areas critical for consciousness are the prefrontal cortex and anterior cingulate, although there are specific neurotransmitters and other brain processes that are necessary for conscious awareness.

The field of neuropsychology also appreciates distinct forms of consciousness, ranging from

comatose to different stages of sleep. Each level is associated with various brain wavelengths and a unique system of neural mechanisms. For example, beta waves are associated with alert wakefulness, whereas delta waves are found during stages three and four of sleep. Sleep, as a state of consciousness, is regulated by many neural mechanisms that work in synchrony, including the secretion of melatonin by the pineal gland. Conscious experience can also be altered by hallucinogenics that act upon and disrupt the usual functioning of neurotransmitter systems.

Rationality/Reason

Rationality is an epistemological approach to knowing the world. It involves logical thought procedures to process information, solve problems, and make decisions, with both inductive and deductive reasoning being key components. The prefrontal lobes, particularly the left inferior and middle frontal gyri, are involved in rational thought, as well as the bilateral frontal, parietal, and occipital cortical regions. A decrease in acetylcholine may contribute to impaired reasoning abilities. Therefore, rationality is not only a way of knowing, but it can also be linked to specific cognitive processes and areas of brain activation.

Mystery

Neuropsychology generally conceives of mystery as the occurrence of experiences and events that do not match known physical or natural laws. Sometimes, these experiences violate known expectations concerning the nature and behavior of physical objects. At other times, they simply extend beyond the known principles that govern the natural world, particularly the explanatory power of the brain. If pressed, the majority of neuropsychologists would argue that laws actually exist to explain these events and experiences but that we simply have not found or explicated them yet.

Perhaps more important is the actual neurological mechanisms involved in the way humans respond to mystery. When encountered with counterintuitive or mysterious phenomena, the brain assigns significance or meaning to the

events. The frontal lobes in particular may be wired with an agency-detection mechanism that is ready to be triggered by novel and unusual information as a way of imputing causality to events. They are also responsible for our theory of mind, namely, the process by which we attribute complex mental representations of intentional mental states to other agents and persons. Activation of the frontal lobes may therefore stimulate the release of personally salient mental representations or cognitive schema that has distinct specifications about causal relations. The actual schema that is activated may depend on one's existing knowledge and belief systems. Some may attribute the mysterious phenomena to coincidence and others to divine intervention.

As this suggests, neuropsychology grants a place to mystery, conceiving of it as events, brain activity, or natural laws that are currently inexplicable but that will likely be explained when our knowledge of the natural and neurological world improves.

Relevant Themes

As the field of neuropsychology continues to grow, more themes and questions are coming available to those in the science and religion engagement. One emerging and salient issue is the actual *effect* of religion and spirituality on brain activity. A substantial amount of literature has been devoted to the relationship between religion and mental health, but the next step seems to involve examining how this relationship impacts actual brain systems. For those afflicted with brain diseases, religion appears to enhance coping and recovery, but does this translate into actual brain changes, and in what way? If these changes in metabolism or neurotransmitter activity do appear, is it also possible to identify the negative effects of destructive forms of religious belief?

A related theme is the way that humans make meaning. Religion is generally a meaning-making enterprise, so a better understanding of religion may be found in continuing to explore and identify those neural substrates involved in

attribution, inferring agency, and constructing a narrative that provides purpose and meaning. This exploration may provide an entryway into further studying the brain systems underlying morality, which itself will invite difficult discussion about the ethics of rehabilitation and repairing disrupted morality, as in the case of those with antisocial tendencies. Behind this may even be a debate about the entire conception of freedom of will and original sin. It seems important that any discussion of sin should consider the impact of brain activity on behavior.

Finally, there are ongoing discussions about multiple methodological issues that continue to need attention. These include understanding how to best operationalize and measure spirituality and religion, as well as understanding which neuropsychological tools are optimal for examining religious or spiritual variables. As these themes suggest, neuropsychology has a unique contribution to the leading edge of the science and religion conversation.

Neuroradiology

Rüdiger von Kummer

Department of Neuroradiology, University
Hospital Carl Gustav Carus, Technische
Universität Dresden, University of Dresden,
Dresden, Germany

Related Terms

Diagnostic neuroradiology; Interventional
neuroradiology

Description

Neuroradiology is a medical discipline devoted to diagnose diseases of the central nervous system, nerves, and muscles in the living human being with imaging techniques, and to treat diseases that can be approached trans-vascular with catheters or percutaneous with needles in close collaboration with Neurology and Neurosurgery. The development of Neuroradiology is connected to the development of imaging and interventional techniques mainly based on x-ray or magnetic resonance techniques. During the first half of the twentieth century, above all, Neurosurgeons were interested to improve the safety and efficacy of their operations by visualizing the pathology that they were going to treat. W. Dandy (1886–1946) had the idea to use air as contrast agent within the cerebrospinal fluid spaces and developed the air encephalography (i.e., indirect imaging of the brain by filling the intracranial fluid spaces with air via a needle), and myelography that showed the shape of the air-filled cerebral ventricles and cisterns allowing checking for compression and shifting by space occupying processes (Davidoff and Dyke 1937). E. Moniz (1874–1955), a Portuguese Neurologist, developed contrast agents that allowed studying the blood circulation through the brain by means of x-ray technique (Cerebral Angiography). Later, other and less toxic contrast agents were developed that allowed the visualization of the spinal

canal (myelography) and cranial cisterns and making cerebral angiography safer. In parallel, x-ray technology improved over time. The most important step with considerable impact on Neuroradiology was the invention of computed tomography by G. Hounsfield in 1972. Computed tomography (CT) revolutionized x-ray technology by exactly measuring the x-ray attenuation of tissues and by the application of computer capacity that calculates repeated attenuation measurements allowing the visualization of soft tissues in a three-dimensional space. For the first time, physicians could see and evaluate the brain and spinal cord and its pathology. Only a few years later, the physical principle of nuclear magnetic resonance – known since 1946 – was applied to medical imaging and achieved images of human tissues with high spatial and contrast resolution. Since then, magnetic resonance imaging (MRI) became the imaging modality with the best potential to explore brain function and pathology, a development that is not yet final (Damadian et al. 1977) (► [Neuroimaging](#)).

Since 1980, the development of microcatheters and other devices allowed approaching the brain and spinal cord via arteries and veins. With this technique, the treatment of stenotic and occluded arteries with the risk of stroke became possible. Moreover, Neuroradiologists now use catheters to treat the sources of intracranial bleeding like aneurysms and arteriovenous malformations and to embolize tumors before surgery in order to reduce the risk of bleeding. With the support of CT, Neuroradiologists learned to exactly puncture sites around the spinal cord in order to take biopsies or inject drug, e.g., for pain relief.

In addition to Neurosurgeons, Neurologists and Radiologists specialized in imaging techniques and interventions for the diagnosis and treatment of the central nervous system. Neuroradiology became finally a subdiscipline of Radiology in many countries like in Germany, but has gained the status of an independent medical specialty (discipline) in some countries like Portugal. In contrast to general Radiology, Neuroradiology focuses on a single organ, the nervous system and muscles, its development, function, pathophysiology, pathology, and

diseases, and is free to apply the most appropriate techniques for research, diagnosis, and treatment.

Self-Identification

Science

Neuroradiology is in its essence applied natural science. Neuroradiologists need to acquire a deep understanding of the anatomy, development, and physiology of the nervous system in order to learn about the law of nature that rules neurological function and diseases. In addition, Neuroradiologists need to critically appreciate the methods they use to observe the nervous system under normal and pathological conditions. This requires open-mindedness, very careful, and unbiased prospective observations with the test of hypotheses, and experience in the methods applied. Neuroradiologists are trained in the use of different imaging modalities, know its limitations, and can thus give a valid and reliable interpretation of medical images that help to understand the function and dysfunction of the nervous system, to predict further disease development and the effect of specific treatments.

Characteristics

Neuroradiology shares similar aims with Neurology ► [Neurology in Europe](#), Neurosurgery ► [Neurosurgery](#), Psychiatry, and Radiology. It is distinct among these disciplines by combining deep knowledge and experience in medical imaging with its application to the special requirements of the nervous system, thus allowing the exploration of nervous function and diseases.

Relevance to Science and Religion

The development of functional neuroimaging including the imaging of focal metabolic changes in association with special brain functions and the imaging of connectivity between brain areas is

highly relevant to the area of “Science and Religion.” The timing of visualized brain function and action, e.g., has provoked questions about the freedom of will.

Sources of Authority

In 1929, C. Dyke became the first full-time American Neuroradiologist and published a classic text on pneumoencephalography. M.M. Schechter developed a completely independent Neuroradiological Unit at St. Vincent’s Hospital in New York. With the support of the National Institute of Neurological Diseases and Blindness, training programs in Neuroradiology were established under Schechter and J. Taveras in 1960. J. Taveras, together with J. Wood, wrote the standard text, *Diagnostic Neuroradiology* in (Taveras and Wood [1964](#)), and became later the first editor of the *American Journal of Neuroradiology*. Now, textbooks on Neuroradiology are available in different languages (Jansen et al. [2008](#)). At the university level, Neuroradiology is now organized in independent departments or divisions in Europe and the United States of America.

Ethical Principles

Neuroradiology is guided by the same ethical principles as other medical disciplines that are the Oath of Hippocrates and the Helsinki declaration of “Good Clinical Practice.” Practice in Neuroradiology follows established guidelines and standard operation procedures based on evidence.

Key Values

The key values of Neuroradiology are the training in reliably interpreting medical images of the nervous system and the experience in guiding catheters into the diseased vasculature of the central nervous system to enable treatment with minimal invasion.

Conceptualization

Nature/World

A Neuroradiologist conceptualizes nature in its broadest sense like other Neuroscientist as equivalent to the material universe or the material world. Manufactured objects and human interactions generally are not considered part of nature. Nature ranges in scale from the subatomic to the galactic and follows laws that can be detected and used to understand nature and the causal relationships within the material world.

Human Being

Human beings are part of nature and here primates in the family Hominidae. Human beings differ from other living creatures in having a highly developed and complex brain, capable of abstract reasoning, introspection, language, and problem solving. Research in and treatment of human beings by human beings require respect and ethical considerations.

Life and Death

Life is a process of organisms, capable of growth and reproduction. Death is the end of life. Neuroradiology helps to determine whether the diseased brain of human beings is irreversibly injured and whether the patient has a chance of survival.

Reality

Reality includes everything that is existent. Neuroradiology as a natural science helps to describe the reality of the nervous system and to reject concepts of nervous function that are not existent.

Knowledge

Knowledge is expertise and skills acquired by a person through experience and education involving perception, learning, communication, association, and reasoning that are complex cognitive processes, which could be followed by imaging in the future.

Truth

Truth is the agreement with reality, on which a Neuroradiologist will rely on. Neuroradiology

as a natural science seeks to define the laws and conditions that rule the nervous system.

Perception

Perception is the active process of attaining awareness or understanding of sensory information ► [Perception](#). Neuroradiology can image structures that enable and process perception, assesses causes of disturbed perception, and contributes to the question which sensory stimuli are realized.

Time

Neuroradiologists rely on the Newtonian time, considering time as part of the fundamental structure of the universe, a dimension in which events occur in sequence. Neuroradiologists use time to sequence events, to compare the duration of events and the interval between them, and to quantify the motion of objects like the blood flow through the brain.

Consciousness

Consciousness is a mental state that allows the perception of the self in relation to other human beings and the universe. Components of consciousness are thoughts, inner language, sensations, perceptions, moods, emotions, dreams, and self-awareness. Neuroradiologists have to deal with patients who have lost consciousness. A loss of consciousness is a symptom of severe brain disease that should be diagnosed as soon as possible in order to avoid permanent brain damage.

Rationality/Reason

Neuroradiology as a natural science is devoted to rationality in the sense of logical validity in understanding nature and its underlying conditions and laws.

Mystery

Mystery as something unexplainable does not exist in the reality of Neuroradiologists. If confronted with a “mystery,” Neuroradiologists like other natural scientists will seek an explanation for this phenomenon ► [Rationality \(philosophical\)](#).

Neurosurgery

Wilhelm E. Eisner
Department of Neurosurgery, Medical University
Innsbruck, Universitäts-Klinik für
Neurochirurgie Innsbruck, Innsbruck, Austria

Description

Today neurosurgery is dedicated in offering detailed surgical therapeutic regimens for the clinical

syndromes caused by diseases affecting the brain, spinal cord, and nerves. Already in Persia, Egypt, Greece, Arabia, and North Europe neurosurgical procedures were performed since more than 10,000 years. The purpose for surgery in ancient times had been for medical or religious reasons. The second half of the nineteenth century was the beginning of modern neurosurgery. The demands for establishing modern neurosurgery were the possibilities of general anesthesia, asepsis, and correct localization of functional areas in the brain. These demands were fulfilled in the second half of the nineteenth century: In 1846, first operation was performed under general anesthesia (JC Warren, WTG Morton), asepsis, by intensive cleaning of the surgeon's hands with soap (J Semmelweis), possibility of exact localization of certain brain areas:

- Sensory motor region (J Rolando)
- Localization of language functional areas (PB Broca, C Wernicke)
- Focal motor seizures (JH Jackson)
- Direct electrical cortical stimulation in awake dogs (G Fritzsche, E Hitzig)

Pioneers in neurosurgery were surgeons and neurologists focusing on surgery of the central nervous system. The leading countries were Germany and England. The names of these pioneers were Ernst von Bergmann, Victor Horsley, Fedor Krause, and Otfried Förster. Ernst von Bergmann wrote the first book on neurosurgery in 1887, *Die Chirurgische Behandlung von Hirnkrankheiten*. Fedor Krause in Berlin used electrophysiological examinations to identify cranial motor nerves during surgery of the cerebellopontine angle in 1899, and he was able to identify first the facial nerve and the current spread through the cerebrospinal fluid intraoperatively. Despite the leading role of German surgery during the Gründerzeit (1920–1961), the development of neurosurgery, during that period, happened in the USA. Harvey Cushing is regarded as the founder of neurosurgery because he founded the first school of neurosurgery in the world. Therefore he was elected and nominated being “The Neurosurgeon of the first half of the twentieth century” by the world federation of neurosurgeons. In the first half of the

twentieth century, the development of neurosurgery went parallel with neurology. Milestones in the development of modern neurosurgery were:

- 1920: foundation of the American Society of Neurological Surgeons
- 1926: foundation of the first European Society of Neurosurgery in England
- 1936: founding of the first scientific magazine on neurosurgery in the world “Zentralblatt für Neurochirurgie” by Wilhelm Tönnis (1898–1978)
- 1950: foundation of the “Deutsche Gesellschaft für Neurochirurgie” (DGNC) in Bonn
- 1951: introduction of the specialist title “Facharzt für Neurochirurgie” in Niedersachsen
- 1956: introduction of the specialist title in all German countries
- 1961: introduction of microneurosurgery by using a operations microscope by T Kunze and SB Doyle
- 1966: first microneurosurgical clipping of an intracerebral aneurysm by JL Pool and RP Colton
- 1972: computed tomography
- 1978: magnetic resonance tomography
- From 1990: neuronavigation

For his achievements in microneurosurgery, Mahmut Gazi Yasargil (July 6, 1925) was elected and nominated as “The Neurosurgeon of the second half of the twentieth century” by the world federation of neurosurgeons.

Throughout Europe, Neurosurgery became a discipline in its own right in the middle of the twentieth century, was treated as a separate entity distinctly from other surgical disciplines such as general surgery or cardiac surgery and other disciplines covering diseases of the brain like neurology, psychiatry, and internal medicine. This development started in the university hospitals followed by the establishment of separate Departments of Neurosurgery in most major community hospitals in the second half of the twentieth century. In Europe and USA, there are about 3,000 neurosurgeons each. Modern Neurosurgery has benefited from advances in imaging. Until the beginning of the 1970s, no direct visualization of the brain tissue was available. The instruments

of visualization of cerebral structures until then were angiography and pneumoencephalography. Since the second half of 1970s, direct visualization of brain tissue was possible by computed tomography (CT), magnetic resonance tomography (MRT), positron emissions tomography (PET), and magnetoencephalography (MEG). Since the end of 1980s, even functional activity of the brain could be visualized by PET, MEG, and MRT. At the end of the nineteenth century, brain functions like motor functions could be already identified by direct electrical stimulation and visualization of the evoked phenomena (Moller 1995). This was pioneered for the broad range of human brain functions by Otfried Foerster (1873–1941) in Breslau. Because of the development of the y-knife by Lars Leksell from Stockholm in the 1950s radiosurgery is possible since 1967. These innovative advanced techniques allow neurosurgeons to treat tumors and vascular malformations without opening the skull of the patients. In the last 20 years, recent developments in endovascular therapy, like the coiling of aneurysms, enable the treatment of cerebral aneurysms without opening the cerebral skull for clipping aneurysms. Neurosurgery treats diseases of the brain, spine, and peripheral nerves. Topics are:

Neurotraumatology: Treatment of traumatic lesions of the head and neck, spine and peripheral nerves by trepanation and hematoma removal, reconstruction surgery of the skull or spine or peripheral nerves, including intensive care medicine.

Neurooncology: Treatment of tumors of the brain, spine, and peripheral nerves, including tumors of adjacent structures like dura mater and bone tissue by resection, biopsy, endoscopic surgery, radiosurgery, and chemotherapy (Yasargil 1993).

Vascular Neurosurgery: Treatment of vascular malformations like aneurysmata, angiomas, vascular occlusion syndrome including ischemic stroke by resection, clipping, endovascular coiling or glueing, plaque removal and bypass surgery (Yasargil 1993).

Functional Neurosurgery: Treatment of movement disorders, therapy resistant epilepsy,

severe psychiatric disorders, central pain syndromes (Lozano 2009).

Surgery for development abnormalities like hydrocephalus, spinal dysraphic disturbances, and others.

Spine Surgery: Removal of herniated intervertebral herniated disk prolapses, spinal stenosis, spinal tumors, spinal vascular malformations, and affection of the stability of the spine.

Peripheral Nerve Surgery: Therapy of nerval entrapment syndromes, tumors of nerves and nerve sheaths, nerval reconstruction.

Therapy forms are Macroneurosurgery, which is neurosurgery as it is used since ancient times. The skull will be opened (trepanation) by stone or metal instruments. Surgery is performed under direct visualization without microscope or other devices to improve the visual perception of the surgeon; Microneurosurgery, ► [Stereotactic Surgery](#), Radio-surgery, Vascular Neurosurgery, Spinal Neurosurgery, Neuroablation, ► [Neuromodulation](#), ► [Neurotransplantation](#), Restorative Neurosurgery.

Self-Identification

Science

Neurosurgery has self-identified, from its very beginning, as a natural science. It sees itself located in a certain scientific area between the field of surgery and neuroscience. The aim of neurosurgery is to enhance the knowledge about the organization and function of the human nervous system as well as their disease-related abnormalities as a basis for surgical strategies to treat diseases of the nervous system. The concepts of understanding the human brain were developed by comparison studies between neurological deficits and neuropathological examinations of the same persons before and after their death. Clinical investigations in experimental animals could enlighten many questions on neurofunctionality. But higher cognitive functions like language and memory for example had to be examined in pre-, intra-, and

postoperative comparison studies following neurosurgical procedures from the nineteenth through the twentieth century until now. Intraoperative examinations could be performed under general anesthesia for motor functions but other functions like sensory functions needed the so-called awake surgery. During awake surgery procedures the skin and the skull of the patients were opened under local anesthesia and examinations took place by using direct electrical stimulation of the human cortex and visualizing the evoked motor phenomena. Higher cognitive functions like language and speech could be identified by electrical inhibition of the function by electrical stimulation of brain areas activated by specific tasks. Otfried Förster introduced that method to the armamentarium of neurosurgery already in the 1930s. Even surgical procedures to alleviate the shaking palsy and other motor symptoms of the Parkinson's disease in the last 60 years gave as deep insights in motor functions of the human brain as gained by experimental animal studies and neuropharmacological studies. Neurosurgical experimentations and neurosurgical studies add scientific information to the field of neuroscience as the fields of neurochemistry, for example. Surgical strategies and methods were evaluated for its content and value for treatment of patients in prospective studies, very often in prospective randomized blinded multicenter studies. This approach let to a broad spectrum of powerful options for the treatment of neurological diseases.

Characteristics

Neurosurgery is distinctive among other specialties of Medicine:

Neurosurgery concentrates on surgical cure or therapy of diseases in and around neuronal tissue. The neurosurgeon faces different causes for therapy. It can be originated in traumatic, oncologic, vascular, neurodegenerative, or malformed circumstances in its development. The decisive moment is the necessity of a surgical intervention; otherwise, severe

damage to the health or life of a human being is apparent. The second decisive moment is that the problem being treated is originated in or around neural tissue like the brain, spinal cord, or nerves. These two effective stages define neurosurgery and distinguish it from other surgical or medical disciplines.

Relevance to Science and Religion

Neurosurgery was and is able to give fundamental information on clinical and basic neuroscience research. It attracted the interest of the world medical community, while trying to identify cerebral functions by intraoperative examinations, for example, in awake surgeries. Most recently attempts have been made by comparison of intraoperative findings and functional neuroimaging to bridge the gap between human brain physiology and cognitive and emotional control of behavior, decision making, communication, and metaphysical experiences. This interdisciplinary discourse between the neurosciences and the humanities is still in its beginning.

Sources of Authority

Authoritative sources in neurosurgery are reputed textbooks, reference books, publications, peer-reviewed scientific papers containing results of prospective randomized blinded studies, the guidelines for good medical practice and evidence-based medicine, and of course the authoritative guidelines of the Medical Societies of neurosurgery, such as the European Society of Neurosurgery or the American Society of Neurosurgery.

Ethical Principles

Neurosurgery is guided by the oath and law of the ancient Greek physician Hippocrates (born 460 B.C.) who is considered the so-called father of medicine. This “Hippocratic Oath” has been

supplemented by the rules of the Declaration of Helsinki of 1971. Now the local, national, and international ethical committees such as the European Ethical Committee are allowing and controlling every study concerning medicine and patients. For animal studies the National Ethical Animal Committee is allowing and controlling every experimental animal study.

Key Values

Compared to other nonsurgical disciplines neurosurgery has the advantage of acute and immediate medical observations and results which are able to give hints or ideas concerning the neuronal functionality and functional distribution in humans. Without the comparative findings between neurosurgery and imaging modalities like functional imaging, it would have been impossible to gain the exhaustive amount of knowledge till now.

Conceptualization

Nature/World

Nature is the entirety of life and matters attending a concrete system of laws.

Human Being

The human being is the most evolved being on earth and is also the only representative of his species (*Homo sapiens*).

Life and Death

Life is determined by cellular activity. It is identified by cellular anatomy and interaction of the cellular organelles. Just amino acids do not make life but amino acids are parts of living systems. Cell groups are able to form an organism with specialized cells in function. All cells are dividing by that the system is growing following a special program and time frame. Death is the cessation of cellular function. The cell will be destroyed chaotically (like in fire) or systematically like in the process of apoptosis where parts of the destroyed cells will be used again.

In human beings we define two forms of death. The first form is characterized by cessation of all cellular activities by stopping nutritive circulatory actions to the whole system causing autolysis of the whole system. The second form of death is the brain death. Here the nutritive circulatory function is still efficient working but the system of cognition and emotion (supratentorial brain and most parts of the brainstem) has stopped its function and the human being is unable to regain consciousness in the future.

Reality

Reality is the world's nature around us as it appears, the life existence in a concrete space at a given time opposite to illusions, dreams, ideas, desires, and feelings.

Knowledge

Knowledge is the understanding of the world reality but is also the experience, the intuition, the conscience, the education, and the instruction. Knowledge is the capacity of creating a concept and analyzing a thought.

Truth

Truth is the knowledge of the reality, excluding errors and conjectures. The truth for a human being is perceptible in the moment where his brain-mind gives his assent.

Perception

Perception is everything happening and coming to one's senses within a time frame of 3 s. Information entering human brain by the five senses are short in duration. The time frame is mostly within a single second or up to a few seconds. If there is no input to the human brain, then this will reset the state of information every 3 s. Because of that the actual being is defined as now in a frame of 3 s. What happened before is the past. What happens later is the future.

Time

Time is a construct like a neuronal network. Astronomy defined a complete cycle of the earth around the sun a year.

Consciousness

Consciousness is the state of intercommunication of a physical being with its surrounding world.

Rationality/Reason

Rationality is a form of human behavior. A human being acts in the way the society demands to. Rationality is in some time an unaccountable and a responsible act. For example a neurosurgeon should remove a brain tumor and not the brain.

Mystery

Mystery is how it happened that a huge cluster of cells has formed organisms and structures like the brain. Each acting and cognitive system runs parallel with little situations of damage to other systems. For example it is a mystery that we are driving in different lanes with high speed on the motorways without collisions every few meters?

Relevant Themes

Neurosurgery is the attempt to cure or influence mechanically brain and nervous dysfunctions and diseases. The process of research to understand brain functions is still ongoing and will be never ending. Neurosurgery is capable to change brain functions of human beings or animals in many ways. Neurosurgery is able to destroy or change the will, the emotions, the perception, and behavior of beings. Because of the responsibility for human beings treatment by neurosurgeons must be governed by ethical rules to help patients regain their quality of life without negative changes in their being and in their personality.

Neurotheology

Andrew Newberg
Thomas Jefferson University, Philadelphia,
PA, USA

Related Terms

[Neuroscience of religion and spirituality](#)

Description

Neurotheology is an emerging discipline that integrates religious and spiritual concepts with neurological and neuropsychological analyses. Thus, both the neurological and theological perspectives must be considered if one is to find the best way of understanding both the human brain and how that brain perceives and experiences religion. Clearly, one of the initial problems with neurotheology as a field is the use of “neurotheology” as a term (Newberg 2010). Too often, the term “neurotheology” has been used inaccurately or inappropriately. Many times, it appears to refer to a study or idea that incorporates neither neuroscience nor theology. Strictly speaking, neurotheology refers to the field of scholarship linking the neurosciences and theology. Neuroscience would thus refer to the empirical study of the central nervous system or brain, and theology would refer to the critical and

rational analysis of a particular religious belief system, specifically one pertaining to God. Of course, both the terms “neuroscience” and “theology” have evolved over time. Neuroscience used to imply the study of nerve cells and their function without a clear regard for behavioral and cognitive correlates. Neuroscience today tends to reach over many different fields including cognitive neuroscience, neurology, psychiatry and psychology, and even social behavior. The tools have also become more advanced including a number of functional brain imaging capabilities for exploring the translational relationship between the brain and various cognitive, emotional, and behavioral processes.

Theology has also changed over time. In a very strict sense, theology is the study of a *theos* or God. Thus, the word “theology” should be reserved for theistic traditions only and, even more specifically, from those arising out of the Greco-Jewish tradition, i.e., Judaism, Christianity, and Islam. However, with the development of comparative theology in the early part of the last century, it became apparent that the nontheistic Eastern religions possessed many of the formal characteristics of the classic Western religions. It became academically fashionable to use the term “theology” for the formal study of any belief system centered on an Ultimate or Absolute, whether theistic or nontheistic. It is now acceptable to speak of a theology of Buddhism, a theology of Hinduism, and even of a theology of Shamanism.

Within each religious tradition, the word “theology” can be used in two senses – natural theology and theology proper (or dogmatic theology). Natural theology is not really theology at all but rather a branch of philosophy. It attempts to prove, or at least prove probable, the existence in reality of God or the “Absolute” by reason alone, without any appeal to Divine Revelation (in the West) or to fairly rare esoteric experiences (in the East). Theology proper represents intellectual deductions from a foundational story or myth (i.e., the primary myth upon which the religion is based) as well as “reasonable” extrapolations upon such a myth. Such extrapolations may also involve the employment of analogical

reasoning and symbolic logic that does not necessarily neatly fit within a logical reasoning pattern. Eventually, theology becomes a process of reflecting upon the way individuals of a particular religion should live out their faith. Depending on how it is applied, neurotheology may be of use in both natural theology and theology proper. The possibility that neurotheology may help to “prove” or “disprove” the existence of God should at least be considered, although this might be quite difficult. Neurotheology may also inform scholars regarding the process of theology proper to help better elucidate how and why human beings come to specific beliefs and understandings about religion and God.

Neurotheology should not be limited to only neuroscience and theology. In reconsidering the term “neurotheology” then, it seems appropriate to allow for expanded uses of the “neuro” component and the “theology” component. It would seem appropriate for neurotheology to refer to the totality of religion and religious experience as well as theology. This ability to consider, in a broad scope, all of the components of religion from a neuroscientific perspective would provide neurotheology with an abundant diversity of issues and topics that can ultimately be linked under one heading. As we shall see, the neurosciences also must be considered in a broad scope to include not only what goes on within the human brain but within the human body as a whole. Furthermore, since mental processes are intimately linked to the brain, the “neuro” component of neurotheology should be considered to include psychiatry, psychology, endocrinology, as well as other macro- and micro-perspectives of the neurosciences. One might even consider variations on the theme of neurotheology to include other hybrid terms such as “neurospirituality,” “psychotheology,” or “biotheology.”

Self-identification

Neurotheology as Pertaining to Science

Neurotheology constitutes a wide variety of scientific endeavors that include cognitive

neuroscience, functional neuroimaging, psychology and behavior, and anthropology (Newberg 2010). With these fields in mind, there are a number of scientific approaches to measuring different aspects of religious and spiritual phenomena. Objective measures of religious and spiritual phenomena that pertain to the neurosciences include a variety of physiological and neurophysiological measures. Recent advances in fields such as psychoneuroendocrinology and psychoneuroimmunology address the important interrelationship between the brain and body (Damasio 1994; Gazzaniga 2000). While this can complicate measures as well as introduce confounding factors, this integrated approach allows for a more thorough analysis of religious and spiritual phenomena.

Several types of measures which have already been reported in the literature include measures of autonomic nervous system activity. These are the most common approaches to specific religious and spiritual practices such as meditation or prayer. A number of studies have revealed changes in blood pressure and heart rate associated with such practices. It is interesting that the actual changes may be quite complex involving both a relaxation as well as an arousal response. Measures of hormone and immune function have more recently been explored especially as an adjunct measure to various clinical outcomes.

Neurophysiological changes associated with religious and spiritual states can be obtained through a number of techniques that each have their own advantages and disadvantages. In general, the primary requirement is that the methodology evaluates functional changes in the brain. However, there are many ways of measuring such functional changes. Early studies of meditation practices made substantial use of electroencephalography (EEG) that measures electrical activity in the brain. EEG is valuable because it is relatively noninvasive and has very good temporal resolution.

Functional neuroimaging studies of religious and spiritual phenomena have utilized positron emission tomography (PET), single photon

emission computed tomography (SPECT), and functional magnetic resonance imaging (fMRI) (Beauregard and O'Leary 2006). In general, such techniques can measure functional changes in the brain in pathological conditions, in response to pharmacological interventions, and during various activation states. Activation states have included sensory stimulation (i.e., vision, auditory, etc.), motor function and coordination, language, and higher cognitive functions (i.e., concentration). The changes that can be measured include more general physiological processes such as cerebral blood flow and metabolism, in addition to many aspects of the neurotransmitter systems. For example, the serotonin, dopamine, opiate, benzodiazepine, glutamate, and acetylcholine systems have all been evaluated in a number of brain states.

Neurotheology as Pertaining to Religion

Neurotheology also requires religion and theology as major contributors to this field of scholarship (Newberg 2010). One important aspect is the importance of utilizing phenomenological assessment of the subjective nature of religion in order to fully understand any potential neuroscientific information. Neurotheology requires as thorough a phenomenological understanding of religions as possible. While whole departments and seminary schools are devoted to the full understanding of religions or a particular religion, basic components of religion such as ritual, community, prayer, meditation, charity, and forgiveness can be evaluated via neurotheology, but only if they are well understood from the religious perspective. Therefore, a substantial amount of information required for neurotheology must be derived from sacred texts of various religions as well as from the theological developments that are derived from them. In addition, neurotheology must focus on the subjective nature of religious and spiritual experiences. This will be important to observe how different religions treat the human psyche and human behavior and also to eventually contrast these concepts with the scientific perspectives in future chapters.

Regardless of the approach one takes toward theological method, it is important to observe the cognitive and emotional elements involved. For example, all theologies are based on a primary faith system. Thus, belief is first and foremost at the foundation of any theology. However, the analytical component can have an emphasis on thought, feelings, experiences, practical behaviors, or other elements that can be related eventually back to various functions of the human mind and brain. Thus, any method of theology can theoretically be evaluated from a neurotheological perspective in addition to its more traditional approach.

Characteristics

Neurotheology is a distinct discipline since it is the only one that directly connects neuroscience to religious and spiritual phenomena. It may draw from information and data from related fields such as cognitive neuroscience, medicine, anthropology, sociology, ethics, philosophy, religious studies, and theology. However, neurotheology appears to have a unique perspective by trying to integrate fully the notion of religion in the context of the human mind. It also has the important opportunity to improve our understanding of both neuroscience and religious and spiritual traditions.

Relevance to Science and Religion

Since neurotheology is a field that specifically describes an integration of neuroscience and religion, it is a field that lies near the heart of science and religion scholarship. The field of neurotheology is also unique in that it can be approached from many other disciplines. Thus, in an academic setting, a psychologist, neuroscientist, or anthropologist can all do neurotheological research while maintaining themselves in their own fields or departments. Neurotheology simply requires adding the "neuro" component to whatever religious issue

is being evaluated or a “theology” component to whatever brain and behavioral issue is being evaluated. Neurotheology has the potential to engage many academic disciplines in fruitful and productive ways. This is also relevant in the healthcare setting in which physicians, nurses, and pastoral care counselors can all turn to neurotheology to address both academic and clinical topics. Thus, neurotheology is highly relevant to the science and religion dialogue, and vice versa.

Sources of Authority

As neurotheology is a multidisciplinary field, it has multiple sources for providing relevant information and data. Certainly, the scientific disciplines can provide objective measures of body and brain function associated with different religious and spiritual phenomena. However, the requirement of subjective information on such phenomena necessitates the use of subjective religious and spiritual experiences, written documents, sacred texts, and human thoughts and feelings as sources of information. These sources all provide the phenomenological information required to develop and interpret neuroscientific data.

There are at least seven paradigms which can readily contribute to the initial operationalization of neurotheological studies. These seven paradigms include (1) the neurophysiology of spiritual interventions; (2) altering spiritual experiences; (3) drug-induced spiritual experiences; (4) neuropathologic and psychopathologic spiritual experiences; (5) spiritual experiential development in infants, children, and adolescents; (6) physical and psychological therapeutic interventions; and (7) neurophysiology of beliefs. After these study designs are considered, the biostatistical issues with such studies can be reviewed.

The Neurophysiology of Spiritual Interventions

The first paradigm involves an experimental spiritual intervention such as prayer or meditation

with concomitant measures of a psychological- and spiritual-dependent evaluation (Wallace 2006). This will help to define and delineate the nature of the spiritual intervention itself. These psychological and spiritual measures can then be compared to simultaneously derived neurobiological parameters, such as electroencephalographic activity, cerebral blood flow, cerebral metabolism, and neurotransmitter activity (Austin 1999; d’Aquili and Newberg 1999). Such measures can be performed with state-of-the-art imaging techniques including positron emission tomography (PET), single photon emission computed tomography (SPECT), and functional magnetic resonance imaging (fMRI). Body physiological scalar parameters such as blood pressure, body temperature, heart rate, and galvanic skin responses (that measure autonomic nervous system activity) can also be measured. Other body physiological parameters such as immunological assessments, hormonal concentrations, and autonomic activity should also be included to complete a thorough analysis of the effects of spiritual interventions.

Altering Spiritual Interventions

A second existing paradigm that might be employed to investigate spiritual experience from a neuroscientific approach uses pharmacological agents or other interventions in an attempt to alter spiritual interventions. Thus, using this paradigm, a previously measured spiritual intervention will be compared to the same intervention with the addition of some intervention. For example, studies might attempt to show the effects of an opiate antagonist on the strength of the subjective experience of meditation or prayer. The effects of transcranial magnetic stimulation, other pharmacological agents, or even surgical procedures (performed for other purposes) could be evaluated. However, it is clear that more extensive studies measuring a number of neurophysiological parameters are required. Other agonists and antagonists may be utilized to determine their ability to augment or diminish spiritual experiences. In addition, the exploration of various pharmacological agents on spiritual interventions may help to delineate

the role of different neurotransmitter systems. Such studies also offer the possibility of measuring dose responses in terms of spiritual interventions.

Drug-Induced Spiritual Experiences

A third paradigm that might be employed utilizes those people whose use of hallucinogenic agents has resulted in intensive spiritual experiences. Since it has long been observed that drugs such as opiates, LSD, and stimulants can sometimes induce spiritual experiences, careful studies of the types and characteristics of drug-induced spiritual experiences, perhaps utilizing modern imaging techniques, may help elucidate which neurobiological mechanism is involved in more “naturally derived” spiritual experiences. Some studies related to the use of such hallucinogenic agents have already been performed, but a more extensive study of such agents, particularly in relation to religious and spiritual experiences, is required. Comparing this paradigm to naturally occurring spiritual phenomena may allow for a better distinction of pathological and nonpathological spiritual experiences. There are obvious ethical and legal considerations with studies such as these (although studies outside of the United States may be more possible). However, subjects who have had pharmacologically induced spiritual experiences can be studied using radioactive analogues of such agents as a means of determining the concentration of receptors and their agonists. Another related approach would be to study the effects of drug withdrawal on spiritual experience.

Neuropathologic and Psychopathologic Spiritual Experiences

A fourth paradigm would utilize patients with various known neuropathologic and psychopathologic conditions (Newberg and Waldman 2009; Koenig et al. 2001; Koenig 1998). Neurological conditions including seizure disorders, particularly in the temporal lobes, brain tumors, and stroke, have been associated with spiritual experiences or alterations in religious beliefs. For example, temporal lobe epilepsy has been associated with hyperreligiosity and religious

conversions. Psychiatric disorders such as schizophrenia and mania also have been associated with spiritual experiences and religious conversions. Delineating the type of pathology and the location of that pathology will aid in determining the neurobiological substrate of spiritual experience. Thus, neuropsychiatric disorders can be an effective tool for the neuroscience of spiritual experience.

Research on pathological conditions has classically been used to elucidate the normal functions of biological systems. Spiritual experiences in psychiatric and neurological disorders may be central to the identification of largely nascent neurobiological systems that subserve “normal” spiritual experience. This presents a crucial distinction to the historic psychiatric implication that spiritual experience is an expression of psycho- or neuropathology. This provides a framework in which normal spiritual experience can occur in pathological and normal conditions and pathological spiritual episodes might occur in individuals with or without psychopathological disorders. However, care must be taken to avoid referring to spiritual experience only in pathological terms or associated with pathological conditions as well as not reducing spiritual experiences only to neurophysiological mechanisms.

Spiritual Development

There has been a fairly extensive literature regarding the developmental aspects of religion and spirituality. These reports consider the overall development of spiritual experience from infancy through adolescence and into adulthood. There is also consideration of the necessary neurocognitive developments for spiritual experience to arise. For example, a more primitive form of undifferentiated faith may occur in infancy, while the more complex aspects of spiritual experience which include cognitive, cultural, and affective components usually require growth into adulthood. Most of these analyses of spiritual experiential development are grounded in psychology. However, neuroscience may be able to utilize these findings and compare them to the development of various brain structures

and neurocognitive processes. This may help elucidate which brain structures and functions are required for various components of spiritual experience. The developmental approach can also be viewed from the end of life perspective. For example, alterations in spiritual functions may be associated with diffuse neuropathological conditions (e.g., dementia). Furthermore, it may be useful to study alteration in spiritual functions that are associated with decrements in neurocognitive functions as well as decrements in physical health.

Physical and Psychological Therapeutic Interventions

There are a large number of ongoing studies which have explored the therapeutic effects of meditation, stress management, prayer, and other related interventions for various psychological and physical disorders including anxiety disorders, hypertension, coronary artery disease, cancer, and the human immunodeficiency virus. While these studies focus on the effects of the intervention on various disease parameters, it may be possible to “piggyback” onto these studies to include measures of spiritual experience and well-being. Utilizing measurement scales already available in the literature, it may be possible to determine the relationship of spiritual experiences and well-being to the intervention as well as to the progression of the disorder. Performing high-quality studies is essential to demonstrating the relationship between spirituality and health especially in light of the various criticisms that have been raised regarding methodological issues with these early studies.

Neurophysiology of Beliefs

This last paradigm considers one of the essential characteristics of spiritual experience which is a sense of belief, faith, or certainty that the experience represents reality. This is what helps differentiate dream states from spiritual experiences which may have similar components. The spiritual experiences are invariably perceived as being real. This sense of certainty is also an integral part of the concept of “faith.”

One can even try to explore the relationship between certain types of beliefs – i.e., religious individuals versus atheists – and how such beliefs are manifested in different brain activity patterns.

Ethical Principles

Ethical principles of neurotheology are similar to that for other biomedical-type studies. The various measures and phenomena to be studied must be made clear to participants in such research, including the potential risks and benefits. There are several interesting issues that are probably unique to neurotheology compared to other types of studies. One issue is that individuals may experience a change in their religiousness or spirituality. The result of participation might be a greater sense of spirituality and religiousness or a reduction in these feelings. Participants need to be aware of these possibilities. It is also important to be clear about the nature and goals of the study since some researchers may have the hypothesis of proving religion to be good or proving it to be bad. To the extent possible, it is important to reveal to research subjects the biases of the researchers. This is similar to the financial disclosures that might be given in more traditional biomedical studies, but in this case represents a kind of “religious disclosure.” It is also important to be clear about the potential implications of neurotheological research. If results would be observed that might support or refute specific aspects of religious or spiritual beliefs, then there could be a significant effect on a group of people or on an ideology. While this may not inherently be a problem, it is important to try to clarify these perspectives as best as possible.

Key Values

An important value about neurotheology as a field and term is that neurotheology should be considered a “two-way street” with information flowing both from the neurosciences to the theological perspective and from the theological

perspective to the neurosciences. In other words, neurotheology should not be considered the “neuroscientific study of religious or theological concepts,” a procrustean trap that many scholars have fallen into. Theology and religion must also be able to freely inform us about neuroscience and how we interpret the human person from a psychological, social, and spiritual perspective. By enabling a free exchange of ideas, data, and information, neurotheology can achieve a very high level of sophistication.

It is also important that neurotheological research should strive to support both practical and esoteric goals of scholarship and research. This notion recognizes the interrelatedness of both types of problems. Thus, neurotheology research may gain as much from a study of religiosity and mental health as an analysis of the meaning of sacred texts in determining the nature of God. Each issue may require its own distinct paradigm in order to arrive at some conclusion, but the results may ultimately have implications for the other.

It is important to continue to advance the scientific evaluation of various aspects of religious experience and practice. Studies relating religiosity to health and well-being as well as neurological studies of specific types of religious phenomena help to provide a foundation of data from which neurotheology can address many different questions. An additional benefit is the ability for neurotheology research to advance scientific methodology in evaluating subjective experience and complex neurocognitive processes. This area of research also helps to advance our overall understanding of the human person and human health from both a biological as well as a spiritual perspective.

Esoteric goals of research may include both philosophical and theological analysis of various types of rational, emotional, and perceptual concepts in the theological arguments. These goals would help to address traditional theological issues relating to the nature of God, the interpretation of sacred texts, and the ability to relate such ideas to human life and behavior. In many circumstances, such an analysis may rely very little on actual neuroscientific data, but rather focus on

theoretical aspects of the human psyche and mind. Esoteric goals may also relate to questions regarding the possible dual nature of the human body and the human spirit. Questions regarding the soul, consciousness, spirit, mind, and brain should all be accessible to the field of neurotheology.

Neurotheology research must allow for new methods, concepts, and conclusions to arise. This notion recognizes the complexity of the field of neurotheology in the context of how this field should proceed from a methodological perspective. The implication here is that the questions involved in neurotheology are so multidisciplinary and complex that existing methods in both science and theology may ultimately be limited in their capabilities. This does not mean that the existing methods should be bypassed. Quite the contrary, existing methods should be the initial approach for neurotheology scholarship. However, should various issues and problems arise that go beyond the ability of current methods, it is critical to be open to the possibility of developing new methods and new paradigms for understanding neuroscience and theology.

It should also be mentioned that a new approach that fully integrates theological and scientific perspectives might be necessary. Such an approach may represent a “contemplative science” in which scholars engage in both contemplative practices such as meditation and mysticism as well as empirical research found in the neurosciences. Several scholars have suggested this path may be necessary for a deeper understanding of the universe. Recognizing inherent limitations in both science and religion, a combined approach, if performed carefully, may provide a methodology for bypassing such limitations.

Conceptualization

Definitions in neurotheology are of particular interest because it is necessary to clearly define various terms in order to be certain about results from research studies. For example, if a study of a particular religious experience points to certain

brain changes, it is important to adequately define what the experience is and how it is characterized by the subjects. However, for neurotheology in a broader context, it is usually best to try to define terms as broadly as possible to begin with and then narrow and alter them according to future findings and scholarship. This dynamic aspect of definitions is crucial to neurotheology as a field. Thus, the definitions offered below are meant as starting points rather than definitive.

Nature

Neurotheology would define nature as pertaining to all things that can be conceived of or perceived as part of the processes of the human brain.

Human Being

The human being would be defined as the sum or integration of the social, psychological, biological, and spiritual dimensions of an individual (Brown et al. 1998).

Life and Death

Life would pertain to the active functioning processes of the human body and brain. When these processes stop, death would occur. However, these definitions would apply specifically to the body, and neurotheology would also potentially allow for a soul or spirit that could transcend the body's functions.

Reality

On one hand, reality might be defined as whatever exists that results in our perceptions, thoughts, and feelings about it. This definition presumes that our perceptions, thoughts, and feelings are not necessarily accurate but are related to whatever reality actually is.

Knowledge

Knowledge would be defined as various objects of thought that we take to be an accurate reflection of the world.

Truth

Truth arguably would be defined as that which is accurate with regard to reality. The problem from a neurotheological perspective is that everything

we know about the world is processed by the brain and hence can never be definitively determined to be true.

Perception

Perceptions refer to our senses and experiences of the world, including the world inside our brain.

Time

Time is the perception of a sequence of events in the world that follow one another in some order. Time might exist in itself, but it is our brain that enables us to determine time as it relates to us.

Consciousness

Consciousness typically refers to self-awareness about the world but can also more specifically refer to a reflexive self-awareness (i.e., an awareness of the self and that self's experiences). Neuroscientific models suggest that consciousness is derived from the functions of the material brain. But neurotheology recognizes that the alternative – that the material brain – may arise from consciousness as is suggested in traditions such as Buddhism.

Rationality

Rationality usually refers to thoughts that appear to follow a regular relationship. The brain has a number of abstract, causal, and quantitative functions that appear to underlie what we typically consider to be rationality, although some have suggested that emotions are also critical to rational thought processes.

Mystery

Mystery would refer to the state of unknowing experienced by the brain as the inability to fully comprehend something. This usually triggers not only a cognitive process but an emotional process as well.

Relevant Themes

Neurotheology is an emerging field of study and has the potential to offer a great deal to our understanding of the human mind,

consciousness, scientific discovery, spiritual experience, and theological discourse. However, neurotheology must proceed carefully upon these various schools of thought, developing clear, yet novel methods of inquiry. More importantly, neurotheology must maintain a healthy, but optimistic, skepticism about the nature of science and religion as it pertains to humanity. All results of neurotheological scholarship must be viewed and interpreted cautiously. However, neurotheology has the potential to revolutionize our understanding of the universe and our place within it.

Neurotology

Pedro L. Mangabeira Albernaz
Associação William House de Otologia and
Instituto Israelita de Ensino e Pesquisa Albert
Einstein, São Paulo, SP, Brazil

Description

Neurotology, also called otoneurology, is a medical discipline devoted to the interface between otolaryngology and neurology, exploring the clinical evaluation and management of the sensorineural systems of hearing and equilibrium and its related research. It deals with all aspects of the auditory and vestibular sense organs and its central nervous system pathways, including auditory sensations and perception, the neurophysiology of balance, including special auditory tests, auditory and other electrical responses, congenital and acquired hearing problems related to both the ear and central nervous system, cochlear implantation and all aspects of the vestibular system. The advent of new surgical techniques related to the temporal bone and its vicinities led to the expansion of the specialty to include facial nerve disorders, intracranial complications of ear disease, and pathological processes of the skull base.

Self-identification

As a branch of otolaryngology and otology, Neurotology is a science and applies traditional medical knowledge and investigational methods in its clinical and surgical approaches and in research.

Characteristics

Neurotology uses special types of clinical assessments that were developed by specialists in Neurotology, and used exclusively by these specialists. These tests explore several areas of the central nervous system and constitute the only available clinical tests of the reticular formation in the brainstem. Neurotologists work frequently in interdisciplinary fashion with neurologists and neurosurgeons and also rely on neural imaging for their studies, but audiological and vestibular tests still constitute the mainframe of the specialty.

Special surgical techniques were developed and are employed by neurotologists to relieve vertigo and remove tumors and other disorders from the temporal bone or its adjoining areas.

Relevance to Science and Religion

Neurotology is mainly concerned with two important functions: hearing and equilibrium. Hearing is the basis of speech, language, and communication and at this time there is a significant involvement of the scientific community in perfecting hearing devices, both prosthetic and surgically implantable. Cochlear implants have become the treatment of choice for profound sensorineural deafness, both prelingual and postlingual. Diseases of the vestibular system are frequent in the population and many new medications and rehabilitation methods have been developed, and several surgical procedures have been developed or perfected. The vestibular sense organs and their central pathways have also become important in the area of Space Medicine, since astronauts have to deal with different gravities and accelerations in their travels.

Sources of Authority

The early anatomists coined the term *labyrinth* to designate the inner ear due to structural complexities that they could see in their dissections. It was surmised that part of these structures were auditory,

but the other structures remained a mystery for many centuries. This is understandable, for the vestibular organs are related to gravity and acceleration, and gravity was only discovered by Isaac Newton in 1687. The symptom vertigo was known, but it was considered a type central nervous system disorder until Prosper Menière, in 1791, published his observations that demonstrated that the sensation of vertigo originated in the vestibular organs. Menière's clinical reasoning on describing his case was certainly influenced by his knowledge of the work of a French neurophysiologist, Jean Pierre Flourens, who had performed experiments in the semicircular canals of pigeons. The name *Menière's disease* is still given to a type of vestibular disorder that affects both the hearing and vestibular sense organs. The systematic clinical study of the vestibular system was established by Robert Bárány, who won the Nobel Prize of Medicine in 1914 for his work. In 1961 Georg von Békésy won the Nobel Prize for his enormous contribution to hearing physiology.

In 1926 Georges Portmann, in France, proposed a surgical technique for Menière's disease, of decompression of the endolymphatic sac, thus pioneering surgical Neurotology. He based his technique on the concept advanced by Knapp that Menière's disease might be due to an increased pressure in the labyrinth comparable to glaucoma in the eye. Endolymphatic hydrops as the underlying pathology of Menière's disease, however, was only identified in 1938 by Hallpike and Cairns.

The surgical era of Neurotology actually began with the techniques created or perfected by William F. House, who standardized the approaches to the internal auditory meatus through the middle cranial fossa and through the translabyrinthine approach. These techniques made it possible to decompress the facial nerve in all of its intratemporal portions and became standard operations for the removal of vestibular schwannomas, meningiomas of the cerebellopontine angle, and glomus tumors. He also perfected Portmann's endolymphatic sac operation and pioneered cochlear implants.

There are many important medical societies concerning Neurotology, among them the American Neurotology Society, Bárány Society,

Politzer Society, and Prosper Menière's Society. Other societies, such as the Collegium Oto-Rhino-Laryngologicum Amicitiae Sacrum and the American Otological Society, are also involved with Neurotology.

Ethical Principles

As for every medical discipline, Neurotology is guided by the ethical laws of Medicine.

Key Values

The key value of Neurotology is alleviating hearing impairment, balance disorders, and facial nerve dysfunction, which considerably affect the quality of life. In addition its surgical techniques have contributed for effective and safe removal of tumors related to inner ear structures.

Conceptualization

Nature/World

Nature is defined as the physical world in terms of landscape, plants, and animals, as distinct from human creation. It also refers to physical constitution and dynamic forces of an individual. The world comprises the planet in which we live and the universe.

Human Being

A biological being with a highly developed brain and complex sensory organs that led to the acquisition of language. This specialty regards language as a specialization of the auditory system and considers human communication, abstract thinking, and the creation of ethics a consequence of the development of language.

Life and Death

Life is the presence of physical functions in a biological system, with capacity for metabolism, growth, reaction to stimuli, and

reproduction, ranging from single cell beings to highly complex plants and animals. Death is the cessation of all physical functions.

Reality

Reality is the totality of things and events.

Knowledge

Knowledge is justified or verifiable belief, as distinct from opinion. It includes information and skills obtained through learning or experience.

Truth

Truth is the reality that underlies facts and circumstances, or a fact that has been proved beyond any reasonable doubt.

Perception

Perception is an awareness of our surroundings that is provided by our sense organs. Neurotology deals extensively with auditory perception and balance perception. The vestibular system is a complex apparatus that obtains information from the vestibular sense organs, the eyes, and the proprioceptive system and works at a subconscious level like a sensory organ. Conflicts of perception may arise. A typical example is that of a person reading a book, sitting in a room inside a ship that is traveling in a calm sea. His eyes and his proprioceptive system inform him that he is still, but his semicircular canals inform him that he is moving. This conflict of perception may lead to seasickness.

Time

Time is a measurable period during which an action or condition occurs. It is one of the physical dimensions of our universe. In Neurotology time not only signals the sequence of events, but also frequency, which characterizes different types of sounds and is analyzed by our auditory system.

Consciousness

Consciousness is the state of being awake and capable of acquiring subjective experience. Vestibular disorders can impair consciousness in varying degrees.

Rationality/Reason

Rationality is the ability to think logically. Neurophysiologists involved with the auditory system look at logical thinking as a consequence of the development of language.

Mystery

To science mystery is something that has not yet been understood; to religion it is often defined as something beyond the possibilities of understanding. The study of the Central Nervous System and sense organs still presents many mysteries, but significant progress has been made by man in comprehending many of its aspects.

Relevant Themes

A critical issue in Neurology as regards "Science and Religion" is the notion that hearing and acquisition of language are fundamental aspects of human life and particularly involved in quality of life. Multidisciplinary teams are intensely involved in solving the problems of deafness and communication disorders, and neurologists are important members of these teams.

Neurotransplantation

Wilhelm E. Eisner

Department of Neurosurgery, Medical University
Innsbruck, Universitäts-Klinik für
Neurochirurgie Innsbruck, Innsbruck, Austria

Neurotransplantation tries to restore neuronal function by transplantation of neuronal tissue like mesencephalic embryonic tissue, dopamine-producing tissue, stem cells, and neurotrophic factors. Until now, there is some evidence that the methods like transplanting dopamine-producing tissue like human pigmented retina cells or transplanting mesencephalic embryonic tissue are effective therapy forms but shame surgery, without transplantation of tissue, proved effectivity too. Therefore, none of the neurotransplantation methods are ready for non experimental usage.

New Age Religions

Justin E. Lane

[Meditation](#); [Metaphysics](#); [Mind](#); [Self-help](#);
[Spiritualism](#); [Spirituality](#); [Theosophy](#)

Description

New Age religions lack a formal social structure as a whole. Any easily discernible social group is usually based on a common interest in a specific topic, such as meditation, healing, or energy, rather than a formal commitment (Albanese 2008). Any social structure usually develops out

of an audience membership or with local teachings from a knowledgeable source. A lot of material familiar to the traditions comes from mass media such as books, videos, and Internet websites and may contribute to the nonsocial structure of New Age religions (Jenkins 2001). There is no set belief system that encompasses all New Age religions traditions; rather, markers such as an emphasis on the mind, metaphysics, meditation, human ability, and science's role in spirituality are common characteristics.

The most recent developments incorporate scientific and pseudoscientific findings as quasi-canonical. These teachings are not distributed in any one book or even a set number of books. Instead, those findings, usually from theoretical physics or psychology, that support the revelations of religions such as Hinduism and Buddhism, Gnostic Christianity, and many tribal religions are promoted; the common themes that link these traditions are originality, in that they are considered older and therefore more legitimate than the established orthodoxy and the esoteric nature of the traditions.

Self-identification

Science

New Age traditions do not identify as a science but often claim a scientific base. Current trends in New Age thought are making an apparent push toward a spirituality based on science dealing with consciousness and the human mind.

Religion

New Age religions self-identify more as “spiritualities” than religions. Although this could simply be a semantic boundary, this distinction is usually made to set New Age traditions apart from traditional or dogmatic religions. Regardless, there are popular religious themes that repeat throughout New Age thought from afterlife beliefs, beliefs of the soul, morality, mortality, and theological debates of god's existence.

Characteristics

The willingness of the tradition to incorporate scientific findings makes it distinctive; the contemporary New Age could be viewed as an interpretive lens through which spirituality can interpret science. On the other hand, New Age religion is so large and sprawling that it serves effectively as an umbrella term encompassing many traditions such as some UFO Religions, neo-paganism, nature religions, some branches of eastern esoterism, and Rosicrucianism, to name a few, and is thus not so much “unique” because it is not any *one* particular tradition (Albanese 2008).

Relevance to Science and Religion

New Age religions are very interested in the study of science and religion. Whereas many researchers are interested in religion from a scientific standpoint, New Age thought stands at the other end of the spectrum, as a religion interested in science. The research of scholars looking into the effects of meditation, neuroplasticity, and evidence for alternative histories are often mentioned in New Age materials.

Sources of Authority

Sources of authority are interesting in that they transcend individual texts to also incorporate teachers (e.g., Ram Das, Gregg Braden, and Deepak Chopra) as well as television shows on New Age topics and video media such as the now popular *What the Bleep Do We Know* (Chasse and Vicente 2005). Channeled messages, such as those from St. Germain and other “ascended masters,” and by the proximate authority of other channelers (e.g., J.Z. Knight, Madame Blavatsky, George Adamanski) (Albanese 2008; Melton 1998). These sources become authoritative through general acceptance or a claim to inspiration by superhuman authority.

Ethical Principles

Prior to World War II, ethical guidelines predominantly paralleled Christianity. After World War II, many New Age groups took on a more globalist ethic being that the repercussions of warfare were now on a global scale. This becomes reflected in such ethical principles as ecological stewardship and secular humanism (Rothstein 2003).

Key Values

Many New Age traditions value self-revelation and knowledge. Acceptance is also highly valued and is reflected in the rejection of traditional dogmas and little to no ingroup/outgroup markers, a possible product of its predominantly asocial nature. Revelation, being a predominant source of authority, has a high value in many New Age groups.

Conceptualization

Nature/World

Generally, these are not well-defined concepts among New Age audiences. Nature can be considered to be our environmental biosphere, as well as a transcendent force in and of itself, similar to concepts of “Gaia” (Albanese 2002, 2008).

Human Being

Most commonly, a human is defined in traditional biological terms. However, there are many types of humans when the entire spectrum of New Age beliefs is taken into account. Some adherents believe that humans can be inhabited by spirits from other entities known as “walk-ins.” Others believe in “new” types of humans, sometimes known as indigo children. These humans have above-average psychological abilities and are ascribed psychic power.

Life and Death

Oftentimes, adherents believe in reincarnation (Albanese 2008). Notions of afterlife may

include beliefs in a physical afterlife, but the main theme is the soul’s ability to “survive” death. However, hell is rarely emphasized even among groups and adherents with heavy Christian influence.

Reality

Reality is a debated subject; common beliefs are that individuals make their own reality, and it is our mind that constructs “reality.” On the other hand, many believe that we only perceive a diluted reality, and that the true nature of reality is hidden.

Knowledge

Knowledge can be defined as what someone believes and the authority for such beliefs is accepted to come from many sources: Revelation from an external source, science, experience, and the receiving of teachings are all considered viable forms of knowledge.

Truth

Truth is a polysemous term within the New Age movement, because it is extremely unique to each group or individual adherent.

Perception

In modern New Age belief, perception is defined as that which the mind interprets from the outside world.

Time

Time is viewed most often as an illusion. This comes from one of two trends in modern New Age thought. The first is the rejection of linear time and the acceptance of cyclical time. The second comes from an emphasis on the mind’s perception of time, where time is subjectively mutable rather than an objective standard.

Consciousness

Consciousness is assumed, although not exclusively by the New Age, to come from the soul through the mind. Although dualism is becoming more debated, adherents seem to inherently accept dualism as shown through beliefs concerning how the soul survives after the body/brain no longer physically functions.

Rationality/Reason

These concepts are highly valued, however they are understood to be constrained in that rationality cannot explain everything, thus revelatory techniques such as channeling are used to fill in the gaps where rationality fails.

Mystery

The idea that there is something else beyond what is readily available through conventional means of understanding or traditional doctrines spawned this movement from its enlightenment roots. The context of the enlightenment as the womb from which science was born, and empiricism at its root, also gave rise to the New Age value of empiricism as a way to unlock the mysteries of “reality.” In contemporary times, the interpretation of scientific findings in light of spiritual beliefs to solve that which one does not know also emphasizes mystery.

Relevant Themes

An additional issue for this tradition concerns methodological authority. Although the tradition employs science, it is not bound by the same review process as science. While revelation is an acceptable form of knowledge for religions, it is not for science; where science stops being able to explain something, the New Age can use revelation to fill in the gaps. Science on the other hand must admit that it does not yet have an answer.

Another issue is whether or not New Age thought is a science or a religion. These debates are not so much theological or scholarly as they are legal. Where the modern world has tried to draw clear lines between science and religion, New Age religions have blurred that line. Some traditions claim that they are a religion as well as a science, where ultimately, both legally and methodologically speaking, they must choose one or the other.

Non-consequentialism

► Deontology

Nondualism

Karim Fathi

Viadrina Europe University Frankfurt (Oder),
Berlin, Germany

Nondualism can be regarded as the very peak of consequent application of dialectical reasoning. Nondualism holds that ultimate truth is not categorizable beyond mutually exclusive categories of thought. The famous opening lines of the Chinese Dao De Jing provide an appropriate example:

The Way that can be told of is not an unvarying way;

The names that can be named are not unvarying names.

It was from the Nameless that Heaven and Earth sprang;

The named is but the mother that rears the ten thousand creatures, each after its kind. (Lao Tzu, translation: Waley).

Accordingly, any concept, implying a separative differentiation is regarded as illusive. Paradoxical statements like “form is emptiness and emptiness is form,” cited from the famous Mahāyāna Diamond Sūtra (Sanskrit: Vajracchedikā Prajñāpāramitā Sūtra) are typical to nondualist statements. It is noteworthy that nondualist statements appear highly paradoxical to conventional thought. Any concept, even the difference between saṃsāra (meaning the cycle of birth, life, death, and rebirth) and nirvāṇa (meaning the liberation from saṃsāra) or absolute and relative truth, is considered to be “non-different.” In Buddhism, nondualism is particularly considered part of Mahāyāna tradition (including, for instance, Zen and Mādhyamaka), and partly also in Vajrayāna Buddhism (for

instance, in the Dzogchen practice). In Hindu philosophy, nondualism is central to Advaita, which is the most influential and dominant sub-school of the Vedānta school.

Consequently, nondualist spirituality does not regard enlightenment as an achievable end of a path (as stressed, for instance, in the nirvāṇa concept of Theravada Buddhism), rather as having always been inherent to the path itself (such as, for instance, in Mahāyāna and Vajrayāna Buddhism). The ultimate truth is therefore regarded as omni-inherent and cannot be separated, even from relative truth.

Non-duality

Carolyn M. Aldwin and Michael R. Levenson
Program in Human Development & Family
Sciences, Oregon State University, Corvallis,
OR, USA

Non-duality is the experience of the fluid relationship between the self and other. It is an immediate awareness that the boundary between self and other is provision at best. Many contemplative psychologies have the experience of non-duality as central to the purpose of meditation and other spiritual practices. Among Sufis this is called unity of being (*wahdat al-wujūd*), in zen it is called *satori*, and in Christian practice it has been called one as unity, or the unity of experience, as in Meister Eckhart. This was expressed extremely well in the song “Echoes” written by Waters, Wright, Mason, and Gilmour (1971):

Two strangers passing in the street,
By chance two separate glances meet,
And I am you and what I see is me.

Nonreductive Materialism

► Nonreductive Physicalism

Nonreductive Physicalism

Nancey Murphy

School of Theology, Fuller Theological
Seminary, Pasadena, CA, USA

Related Terms

[Emergent monism](#); [Nonreductive materialism](#)

A Survey of Terms

Both “materialism” and “physicalism” have been used to refer *both* to theories of human nature and to a worldview or metaphysical system. In the latter case this involves the denial of the existence of God and any other kind of nonmaterial being. Although “physicalism” is sometimes used in this sense, it is a newer term and so does not have the strong atheistic connotations of “materialism.”

What is at issue in this entry is a theory of human nature. First, physicalism is a denial of body-soul or body-mind dualism. Second, the term “nonreductive” signals denial of the supposition that physicalism also entails the absence of human meaning, responsibility, and freedom. So it is easy to say what nonreductive physicalists are against. It is more difficult to give a positive account. One complication is that there are a wide variety of positions that go under the heading of nonreductive physicalism (hereafter NRP), and there are also a number of positions that are quite similar to NRP that go by different names.

In philosophy of mind, NRP is the most common term for this set of positions but John Searle calls his view biological naturalism (Searle 1992). Among scholars who consider the relations between theology and science a common term is “emergent monism” (Russell et al. 1999). However, NRP is a preferable term because, while “monism” is a proper contrasting term for “dualism,” it means that humans are composed of only one *kind* of substance, but does not tell us whether that substance is physical or something else. Furthermore, while philosophers have done

a good job of distinguishing and defining different kinds of reductionist theses, there has (so far) been less agreement about what “emergence” means. So what do nonreductive physicalists believe about human nature? For dualists the concept of the mind or soul serves the purpose of explaining what we might call humans’ higher capacities. These include a kind of rationality that goes beyond that of animals, as well as morality and a relationship with God. A reductive view concludes that if there is no mind or soul, then people must not be truly rational, moral, or religious; what was taken in the past to be rationality, morality, and spirituality is really nothing but brain processes.

The nonreductive physicalist says instead that if there is no soul, then these higher human capacities must be explained in a different manner. *In part* they are explainable as brain functions, but their full explanation requires attention to human social relations, to cultural factors, and, most importantly, to God’s action in human life.

Historical Developments

At the beginning of the modern period (approximately 1650), there were two major options for understanding human nature. One was René Descartes’s dualism of body and mind or soul (“mind” and “soul” were nearly equivalent in Descartes’s work; it was only later that their connotations diverged). The other was Thomas Hobbes’s reductive physicalism: Hobbes denied the existence of a nonmaterial element constituting human nature, and asserted that human thought and behavior could all be reduced to physics. Idealist-monist positions played an important role in philosophy during the nineteenth century, but in the twentieth century, the primary options were again substance dualism and physicalism.

Several important developments occurred in the latter half of the twentieth century that have implications for theories of human nature. First, reductionism had been considered a highly desirable approach to science, particularly by positivist philosophers of science. They employed the

model of the hierarchy of the sciences, the sciences reflecting increasingly complex systems, each system composed of entities from the next level down. Thus, chemistry studies systems composed of the physicists' atoms; the various levels of biology study larger and more complex systems of biochemicals. The positivists' hope was that higher levels, including psychology and sociology, could be reduced, and thereby explained, on the basis of laws of the lower levels. Since the 1970s this strategy has increasingly been called into question (as will be described below).

A second change was in understandings of philosophical method. Most arguments for dualism were based on conceptual analysis: The concepts of *mind* and *brain* are different, so it is an error to attribute mental properties or capacities to the brain. Conceptual analysis is now being rejected because of its assumption that empirical developments are irrelevant to philosophical arguments. In particular, philosophers of mind are increasingly looking to the cognitive neurosciences for evidence that the brain (suitably contextualized) is indeed the source of all mental capacities.

Third, there is now a greater degree of specialization in philosophy. Discussions in philosophy of biology have led to different resources for understanding a nonreductive version of physicalism than those most often employed in philosophy of mind. There are in fact two ways of arriving at a physicalist position. One is to begin with a dualist view such as that of Descartes and then simply subtract the mind or soul. The alternative arises largely from philosophy of biology and, in particular, from the recognition that, just as life has appeared as a consequence of increasingly complex organization, so too have sentience and consciousness. In general this has been the approach of those involved in religion and science discussions in the West.

Anti-reductionist Developments

The most significant criticisms of causal reductionism (and thereby of epistemological

reductionism) fall into three stages: an early emergentist movement (from approximately 1920 to 1950); the exploration of the concept of downward causation or whole-part constraint (beginning in the 1970s); and, currently, an account of causation that combines both downward causation and emergence.

The idea of emergence was proposed in the philosophy of biology as an alternative both to mechanist-reductionist accounts of the origin of life and to vitalism. The vitalists claimed that in order to get life from inorganic matter something like a vital force or *entelechy* (a quasi-aristotelian notion) needed to be involved. Emergentists, such as Roy Wood Sellars, argued that the increasingly complex organization, as one ascends the hierarchy of systems, accounts for the appearance of new kinds of entities with causal powers that cannot be reduced to physics. The organic emerges from the physical; so too do the levels of the mental or conscious, the social, the ethical, and the religious or spiritual.

Sellars claimed that the ontological imagination was stultified at the start by the picture of microscopic billiard balls. In contrast, he argued that organization and wholes are genuinely significant; they are not mere aggregates of elementary particles. Reductive materialism overemphasizes the "stuff" in contrast to the organization. Matter is only a part of nature. "There is energy; there is the fact of pattern; there are all sorts of intimate relations." "Matter, or stuff, needs to be supplemented by terms like integration, pattern, function (Sellars 1970, pp. 136–138)." With hindsight we can see that Sellars and some of the other emergentists were exactly right; however, their arguments did not prevail against the reductionist philosophers of science.

In the 1970s psychologist Roger Sperry and philosopher Donald Campbell both wrote specifically about downward (or top-down) causation. On some occasions Sperry wrote of the properties of the higher-level entity or system *overpowering* the causal forces of the component entities. The notion of overpowering lower-level causal forces rightly raised worries regarding the compatibility of his account with adequate respect for the basic sciences.

Donald Campbell's work has turned out to be more helpful. Here there is no talk of overpowering lower-level causal processes, but instead a non-mysterious account of a larger system of causal factors having a *selective* effect on lower-level entities and processes. Campbell's example is the role of natural selection in producing the remarkably efficient jaw structures of worker termites. His example is meant to illustrate four theses. The first two give due recognition to bottom-up accounts of causation: First, all processes at the higher levels are restrained by and act in conformity to the laws of lower levels, including the levels of subatomic physics. Second, the achievements at higher levels require for their implementation specific lower-level mechanisms and processes. Explanation is not complete until these micromechanisms have been specified.

The third and fourth theses represent the perspective of downward causation: Third, "[b]iological evolution in its meandering exploration of segments of the universe encounters laws, operating as selective systems, which are not described by the laws of physics and inorganic chemistry." Fourth:

Where natural selection operates through life and death at a higher level of organisation, the laws of the higher-level selective system determine in part the distribution of lower-level events and substances. Description of an intermediate-level phenomenon is not completed by describing its possibility and implementation in lower-level terms. Its presence, prevalence or distribution (all needed for a complete explanation of biological phenomena) will often require reference to laws at a higher level of organisation as well (Campbell 1974, quotation at 180).

It appears that little was written on downward causation until the idea was taken up by philosophers of mind in the 1990s. Robert Van Gulick made an important contribution by spelling out in more detail an account based on selection. The reductionist's thesis is that the causal roles associated with the classifications employed by higher-level sciences are entirely derivative from the causal roles of the underlying physical constituents. Van Gulick argues that even though the events and objects picked out by higher-level

sciences *are* composites of physical constituents, the causal powers of such an object are not determined solely by the physical properties of its constituents and the laws of physics. They are also determined by the *organization* of those constituents within the composite. And it is just such patterns of organization that are picked out by the predicates of the higher-level sciences.

These patterns have downward causal efficacy in that they can affect which causal powers of their constituents are activated. "A given physical constituent may have many causal powers, but only some subsets of them will be active in a given situation. The larger context (i.e. the pattern) of which it is a part may affect which of its causal powers get activated . . . Thus the whole is not any simple function of its parts, since the whole at least partially determines what contributions are made by its parts."

Such patterns or entities are stable features of the world, often in spite of variations or exchanges in their underlying physical constituents. Many such patterns are self-sustaining or self-reproducing in the face of perturbing physical forces that might degrade or destroy them (e.g., DNA patterns). Finally, the selective activation of the causal powers of such a pattern's parts may in many cases contribute to the maintenance and preservation of the pattern itself. Taken together, he says, these points illustrate that "higher-order patterns can have a degree of independence from their underlying physical realizations and can exert what might be called downward causal influences without requiring any objectionable form of emergentism by which higher-order properties would alter the underlying laws of physics. Higher-order properties act by the *selective activation* of physical powers and not by their *alteration* (Van Gulick 1995, quotations at p. 251 and 252)."

From Van Gulick's account we can see that evading causal reductionism requires the recognition that higher-level entities and systems have emerged (evolved) from lower, and that these entities can be somewhat independent of the causal processes of their constituents, thereby manifesting new, higher-level causal capacities. The sort of organization and selection of

lower-level causal processes that Van Gulick describes calls for new concepts, and, in fact, represents something like a paradigm change across the sciences. This is the shift from thinking in mechanistic terms to thinking in “systems” terms.

Alicia Juarrero describes the changes required to understand complex systems. One has to give up the traditional Western philosophical bias in favor of *things*, with their intrinsic properties, for an appreciation of *processes* and *relations*; the components of systems are not things, but processes. So, for example, from a systems perspective, a mammal is composed of a circulatory system, a reproductive system, and so forth, *not* of carbon, hydrogen, calcium. The organismic level of description is *decoupled* from the atomic level. Systems are different from both mechanisms and aggregates in that the *properties* of the components themselves are dependent on their being parts of the system in question. They affect one another not by mechanical pushes, but by the fact that they are internally related to one another, such that a change in one automatically changes the other. These relations she calls context-sensitive constraints (Juarrero 1999).

The concepts drawn from nonlinear dynamical ► [systems theory](#) provide the resources needed for understanding the emergence of the complex systems that then exercise downward constraint on their own components. Nonlinear systems are those in which the current state affects the development of each future state. Some such systems are wildly unstable, some entirely stable, some (chaotic systems) fluctuate in a patterned manner, and, finally, some (far from thermodynamic equilibrium) jump to higher forms of organization.

Terrence Deacon has distinguished among three types or levels of emergence. There is no emergence in mere aggregates, though an aggregate does have one sort of global properties. For example, the weight of a volume of liquid is a simple addition of the weights of its molecules. The important difference between an aggregate and a system is that in a system it is *relational* properties of the constituents (as opposed to

primary or intrinsic properties) that constitute the higher order. In such cases additional configurational and distributional information is needed to account for the higher-order properties. Deacon includes here the viscosity of liquids, turbulence in large bodies of water, and typical feedback systems such as a thermostatically controlled heating system. This he calls first-order emergence. In Juarrero’s terms, the relations among components impose constraints on the system. Because fluctuations in such systems are dampened out across time, it is possible to give (rough) reductionistic accounts of their behavior.

Second-order emergence occurs when there is symmetry breaking or the *amplification* of a fluctuation rather than dampening. Systems in which this occurs are nonlinear; their history matters. There are simpler and more complex versions of such systems. The simpler sort is self-organizing, in that higher-order patterns selectively constrain the incorporation of lower-order constituents into the system or select among possible states of the lower-level entities (this is Van Gulick’s point, as well). More complex second-order emergent systems are also autopoietic: They change the lower-order constituents themselves. Examples of the simpler sort are the Bénard phenomenon (the development of orderly convection rolls in a heated liquid), a thermostat that amplifies rather than dampens feedback, and the development of a snowflake. An autocatalytic cycle is of the more complex sort in that the system manufactures some of its own components. All life involves second-order emergence of the more complex sort.

Deacon distinguishes between first- and second-order (as well as third-order) emergence in terms of what he calls “amplification logic” or “the topology” of causal processes. In systems without emergence, global properties are all produced bottom-up (or by means of *local* interactions with boundaries – e.g., a water molecule constrained by the presence of the surface of the container). In first-order emergent systems there is “nonrecurrent” causal architecture: a simple bottom-up and top-down relation in which global properties of the system (e.g., density of

components) makes a difference to the relations among components and thus to the behavior of the whole system.

Second-order systems have more “tangled” or “recurrent” causal architecture as a result of the amplification of lower-level fluctuations. This amplification changes the total state of the system in a way that makes a decisive difference for the future development of the system. This can lead to new orders of complexity. Deacon’s second-order emergent systems are the simplest of those that Juarrero describes as being driven by context-sensitive constraints: what happens before changes the probabilities for future behavior of the components.

Third-order emergence involves the interaction among three levels and appears (naturally) only in the biological realm. Here a variety of second-order forms emerge, and are selected (constrained) by the environment, but in such a way that a *representation* of its form is introduced into the next generation. The simplest example is the evolutionary process. The micro-level (the genome) in interaction with the organism’s environment directs the construction of the organism (the mid-level), whose reproductive fate is determined top-down by the environment (top level). The preservation of information regarding the organism’s success in the environment is the means by which a relatively stable population of successful organisms can be produced, within which future fluctuations appear. Some of these may be amplified (preserved and reentered into the system) by means of interaction with the environment, thus enabling the appearance of still higher degrees of complexity. Deacon describes such systems as exhibiting recurrent-recurrent causal architecture: Over time, a two-stage process of emergence occurs that results in downward causation not just from top to mid-level, but from top to bottom (environment to genome) (Murphy and Stoeger 2006).

Thus, we can see that Campbell’s example of downward selection of termite jaws is in fact an example of Deacon’s third-order emergence. The development of systems theory, theories of self-

organization, nonlinear mathematics, far-from-equilibrium thermodynamics, and, finally, Juarrero’s concept of context-sensitive constraints gives us the conceptual tools to explain why the whole process could never in principle be reduced to the laws of biochemistry, let alone to the laws of physics.

Significance for Philosophy of Mind

Richard Rorty wrote that it is pictures rather than propositions, metaphors rather than statements, that determine most of our philosophical convictions (Rorty 1979, p. 12). Discussions of reductionism in philosophy of mind have been stultified by an unhelpful picture, which is a major obstacle to understanding downward causation in that sphere. Psychology is above biology in the hierarchy of the sciences; mental properties are higher-level properties than brain properties. So we create a picture such as the following, in which *M* and *M** represent mental properties, *B* and *B** represent brain properties, and the arrow represents the presumed causal relation between the brain properties. The vertical lines usually represent the (now fashionable) ► [supervenience](#) relation; or, in other words, the mental properties are physically *realized* by the brain properties.

With this picture available, philosophers of mind such as Jaegwon Kim can ask what causal work is left for *M*. Here is Kim’s tri-lemma: One possibility is to give up on *any* causal role for the mental – the mental is epiphenomenal – and this amounts to reductive physicalism. Another is to count both *B* and *M* as sufficient causes of *B** (and *M**) but this would amount to causal overdetermination, which Kim simply dismisses as “absurd.” Finally Kim considers that there may be some form of downward causation from *M* to *B** (i.e., *M* and *B* are the jointly sufficient

cause of B^*), but he rejects this possibility because it “breaches the causal closure of the physical domain.” And

...to give up this principle is to acknowledge that there can in principle be no complete physical theory of physical phenomena, that theoretical physics, insofar as it aspires to be a complete theory, must cease to be pure physics and invoke irreducibly non-physical causal powers—vital principles, entelechies, psychic energies, *elan vital*, or whatnot. (Kim 1995, quotations at 208 and 209)

Thus, Kim opts for reductive physicalism, claiming that mental properties are causally efficacious only to the extent that they are reducible to physical properties.

This simple little drawing is one of the major *obstacles* to solving the problem of neurobiological reductionism because, as Deacon has pointed out, the relations of mental phenomena to physical phenomena cannot be understood in terms of simple supervenient emergence. In sum, third-order (evolutionary) emergence contains second-order (self-organizing) emergence as a limiting case, which in turn contains first-order (supervenient) emergence as a limiting case. For this reason it is insufficient to describe mental phenomena as merely supervenient on cellular-molecular interactions. One needs to appreciate the many levels of embedded evolutionary emergent processes characteristic of brains, as well as the fact that typical mental events (consciousness experiences) can only have meaning insofar as they are contextualized within complex systems of human culture (Murphy and Brown 2007). Without this more complex account of third-order emergence and the recognition of the embeddedness of the brain in the physical and social environment, it is not surprising that no sense can be made of how a mental event could have downward causal effects on the brain.

Significance for Religion and Science

The topic of ► [nonreductive physicalism](#) is an important one for those engaged in science and

religion dialogue, especially in the West. In the modern liberal Protestant tradition, it has been common to argue that science is intrinsically irrelevant to religion and theology, because their aims are so different. However, in the case of theories of human nature, this division is clearly untenable. For centuries Christian theology (and often Jewish and Muslim thought as well) has taught (or presupposed) a dualist account of the human being, largely under the influence of Greek philosophy. Informal surveys show that the majority of lay believers in the West hold either a dualist or trichotomist (body, soul, and spirit) account of human nature.

Meanwhile science has increasingly made dualism and trichotomism untenable. The development of modern physics created the problem of mind-body interaction, and most philosophers now judge this problem to be insoluble. Evolutionary biology established the continuity of humans with other animals. If animals have no immaterial minds (as most modern thinkers have assumed), then it is difficult to see why it should be thought that humans do. Finally, the cognitive neurosciences are increasingly explaining all of the capacities once attributed to the mind or soul in terms of very specific brain regions and systems.

Christian and Jewish biblical scholars and historians have long argued that dualism was not a part of early Jewish or Christian teaching. The biblical account portrays humans as unitary beings, although manifesting a variety of dimensions or aspects – physicality, emotion, rationality, spirituality – all understood in relational terms. So one important role for the discussion of NRP in religion-science dialogue is to bring to popular awareness the large-scale rejection of dualism among Western Christian scholars. It is crucial to argue against reductionism, since a reductive physicalism, denying the genuineness of all higher human capacities, would be entirely unsatisfactory from a religious point of view.

In addition, scholars involved in the theology-science dialogue have made significant contributions to the development of nonreductive versions of physicalism. A distinction was made above between two routes toward a physicalist

account of human nature. One, typical of earlier contributions to philosophy of mind, begins with something akin to Cartesian dualism and then “subtracts” the mind or soul. The other arises from consideration of the hierarchy of the sciences (and correlative hierarchy of complex systems), with the recognition that higher-level systems are *generally* not reducible to their lower-level components.

Ian Barbour was perhaps the first to introduce this set of ideas to theology-science scholars and to argue that humans be understood in terms of their position in this hierarchy. In *Issues in Science and Religion* Barbour claimed that “an interpretation of levels can contribute to a *view of man* which takes both the scientific and the biblical understanding into account (Barbour 1966, p. 360).”

Arthur Peacocke made significant contributions, accepting a similar account of humans as part of a nonreductive hierarchy, and also making current scholars aware of earlier work on emergence and downward causation. Finally, he made his own valuable contributions to understanding both downward causation and emergence. He argued that a better term for downward causation is “whole-part constraint.” His writings presupposed the understanding of complex dynamical systems, briefly described above, along with the role of contextual constraints (rather than efficient causes) by which the whole affects its constituents. In his final publications he sketched out an approach to theology that locates the human person as a player in the higher-level emergent system that is the church in relation to God; this system, then, exerts whole-part constraint on the individuals who participate.

Numinous/Numinosity

Sharon L. Coggan

Department of Philosophy, University of
Colorado Denver, Denver, CO, USA

Based on the Latin term “numen,” little deity, it refers to the quality of an experience that produces awe, amazement, the uncanny, thrill, and rapture. The numinous is ineffable, unexplainable, and indefinable. It is the experience that produces the chill down one’s spine as one reacts to something that has an extraordinary impact. The numinous experience is thought to be at the very fountainhead of “religion” and “spirituality.” It can be experienced in both positive and negative forms, as in respectively, the experience of the glory of God, as in the lyric “mine eyes have seen the glory of the coming of the Lord,” and negatively in the experience of terror, as in the phrases, the “fear of God,” or the “dark night of the soul” of the mystics. Here the raw, unmediated experience of God is so highly charged as to burn the recipient, so that they look upon the Lord and do not survive it.

Nuptial-Marian Ecclesiology

Andrea Hollingsworth

Department of Religion and Philosophy, Berry
College, Mount Berry, GA, USA

Ecclesiology is the branch of Christian theology that is concerned with the structure, constitution, practices, and functions of the church. The descriptor “nuptial-Marian” refers to Balthasar’s belief (not original to him) that Mary the mother of Jesus expressed to God a perfect bride-like response of faith, and that her

assent is the archetype and paradigm of the faith response of the entire church.

Nyāya

Karim Fathi

Viadrina Europe University Frankfurt (Oder),
Berlin, Germany

Nyāya (Sanskrit for “recursion,” used in the sense of “syllogism, inference”) is the name given to the school of logic in Hindu philosophy. It is one of the six orthodox or *astika* schools of Hindu philosophy.

Nystagmography

Pedro L. Mangabeira Albernaz

Associação William House de Otologia and
Instituto Israelita de Ensino e Pesquisa Albert
Einstein, São Paulo, SP, Brazil

An electronic equipment to record eye movements, *nystagmus*, either by measuring the corneal-retinal potential, *electronystagmography*, or by means of infrared optical devices, *videonystagmography*.

Nystagmus

A movement of the eyes that has a *fast* phase, which originates in the reticular formation, and a *slow* phase, which originates in the vestibular sense organs. Physiologically it is designed to provide adjustment of the eyes to head position and/or movements. In disorders of the vestibular system, it acquires distinct characteristics.

Objectivity in the Human Sciences

Sharon Rider

Department of Philosophy, Uppsala University,
Uppsala, Sweden

The notion of objectivity is intimately tied to key issues in *epistemology* and the philosophy of science. The most general formulation of the issues raised in connection with objectivity in modern discussions concerns the extent to which the object of knowledge is empirically and neutrally given (a view associated with the *empiricist* tradition, see Popper 1963) and to what extent it is itself already “theory-laden,” that is, a product of scientific practice and its criteria for determining what constitutes evidence, justification, and proof (Polanyi 1958) as well as what constitutes a scientific problem. This view is associated, in different ways, with *pragmatism*, *structuralism*, *poststructuralism*, and ► *hermeneutics*. Formulated in this way, this question has far-reaching implications for our concepts of *science*, *rationality*, *knowledge*, *certainty*, and ► *truth* (Foucault 1977).

At the same time, there is a great deal of room for interpretation with regard to the meaning of objectivity. Depending upon in which sense it is used, the answer to the question formulated above will be different. The following is a partial list of senses in which the term is commonly used:

Impartiality

Intersubjective testability

Value-neutrality

Generalizability

Scientific consensus

Empirical reliability and predictability

Facticity

Truth (correspondence to reality)

Rationality

What should be noted here is that already this short and incomplete list raises questions. Impartiality and value-neutrality describe a trait of the scientist(s), while generalizability and intersubjective testability are rather methodological attributes of scientific claims or theories. Empirical reliability and predictability say something about the consequences or results of a theory or claim in use, while scientific consensus describes a social fact regarding the practice of the community of investigators. Thus the question of objectivity can be raised in different senses: is it being attributed to a state affairs, the scientist, the scientific community, the methods of science in practice, the goal of scientific practice, or the consequences of scientific practice? What is it that we are calling objective in science: its objects, its hypotheses, its explanations, its descriptions, its results, its methods, its theories, or some combination of these?

The notion of objectivity becomes particularly complex with regard to the human studies or cultural sciences because there is debate as to whether objectivity is possible in any of these senses, or, depending upon what one means by it, if it is even desirable. The human studies are

defined, in contrast to other fields of inquiry, by a specific feature of their object(s) of study: they involve human actions, beliefs, artifacts, and intentions, as well as the meaning conferred to these actions, beliefs, artifacts, and intentions by the object being studied (human beings) (Collingwood 1940; Dilthey 1991). Yet what is to be grouped as “social science and the humanities,” on the one hand, and “natural science,” on the other, depends upon methodological differences which are in themselves largely contingent upon historical and cultural factors. Psychology and many of its daughter disciplines (e.g., the educational sciences) are usually, but not necessarily, grouped among the social sciences, while psychiatry belongs properly to medicine. The difference has to do with whether the emphasis is placed on explanations in terms of mechanisms in nature, such as neurochemistry, or on the social aspect, that is, intention and meaningful action as such, that is, on agency (including things such as authorial intention, interpretation, etc.). Another way of putting the point is to say that causes and functions are involved in the explanation of natural phenomena, while reasons are involved in the cultural artifacts and human action. But this distinction is not readily accepted by all philosophers or social scientists; to the contrary, some claim rather that social, historical, and cultural studies can only attain objectivity, and thus be construed as genuine sciences, to the extent that they explain social and cultural phenomena in terms of causes or functions.

But even accepting such an objection, it is clear that cultural artifacts are distinct from natural phenomena insofar as they are tied to human practice and action. Using the latter as a defining characteristic of humanities and social sciences, we can ask to begin with what sort of scientific demands are implicitly or explicitly involved in research practice, that is to say, which *norms* guide research in the human studies. To begin with, there is a methodological demand that the investigation and its results be open to intersubjective examination and analysis. This means that the study must make clear what material is being studied, provide sources so that these can be

checked, and explain the basis upon which the selection of material was based so that even the starting points of the investigation can be analyzed and scrutinized by other researchers. In short, the scientific norms of the scholarly community determine which means are appropriate for arriving at an acceptable result; this can mean, among other things, that one can use scientific norms to show that certain things cannot be shown scientifically or that the means at our disposal are not sufficient for arriving at certain desired aims. The objective validity of the study then lay in its success in providing an account that any expert in that field of study would accept as the correct result given the method and materials (Weber 1949).

This sense of objectivity is tied to the notion of value-neutrality, which is the requirement that the political or moral values of the researcher or research community do not steer the method, selection of material, or criteria for valid argumentation. In other words, while we as social scientists and humanists are necessarily ourselves a product of certain social relations which guide the sort of questions we ask and the interest we have in them, for a study to be scientific, it must conduct the investigation regardless of how we may evaluate the conclusions that must be drawn (Merton 1968). For example, whatever a political scientist may feel about the war in Iraq, her political views ought not color her investigation of its causes. To allow her own convictions to guide her methods and choice of material would be to disavow the goal of objective investigation, the very aim of science as an institution. This sense of objectivity, however, has been called into question as both a desirable ideal and as a practical possibility by researchers influenced by *poststructuralism*, *postcolonial theory*, and *gender theory*, among others.

Much of the contemporary discussion regarding the possibility or even desirability of objectivity in the study of culture and society has been colored by the tradition of theory of science that has *positivism* as its starting point. The positivist doctrine that has most influenced the discussion is the distinction between fact and value or

descriptive and normative statements. The point of the distinction is to separate that about which we can have objective (that is to say, scientific) knowledge and subject matter that is by definition subjective, a matter of preference, taste, emotional response, social indoctrination, or cultural habit. But this doctrine met with the criticism that such a distinction is not and cannot itself be a matter of objective fact, given its own definition of objectivity, but rather expresses the values, preferences, emotional responses, and cultural habits of a certain (dominant) group during a specific historical period in a determinate social context. If this criticism is correct, then the distinction as a general principle cannot be upheld. As a result, many theorists in the humanities have drawn the conclusion that objectivity, at least with regard to social and cultural artifacts, is not possible; further, the aim itself, according to some, leads to dogmatism, parochialism, and partiality in research. What should be noticed here is that the rejection of the possibility of objectivity in human studies assumes the positivist sense of objectivity; it is this notion, the idea that statements fall into two categories, objective or subjective, fact or value, descriptive or normative, that has been called into question. Nonetheless, there is room for further consideration regarding what sense, if any, can be given the notion that a scientific study of history or art or society differs substantially and intrinsically from mere preference, opinion, belief, or tradition. In short, the question remains as to whether there is or can be some sense of objectivity which describes the scientific enterprise in these fields and distinguishes it from expressions of taste, ideology, or faith.

Some historians of science have argued that for over a century we have been under the spell of a mechanical or automatized notion of objectivity, in which the ideal is that there should be no trace of human judgment in scientific practice or results (Daston and Galison 2007). If this dominant sense of objectivity is dispelled, the rejection of the positivist notion of objectivity does not lead inexorably to relativism. Another sense of objectivity would be that insofar as a social or

cultural phenomenon is a phenomenon, that is, something that is a recognizable object of consideration, it can be studied as such. Phenomena such as belief systems, works of art, and social institutions can be studied for a better understanding of their significance, what they mean. (Gadamer 2004; Winch 1958) In this view, the objectivity of the study resides in their being phenomena at all, something that can be recognized as meaningful. The objectivity of the results of the study consists in the intersubjective possibility of assessing the extent to which the results follow from the framing of the question, the handling of the relevant material, and the rigor of the argumentation. This sense of objectivity is not absolute, but rather expresses an ideal at which all scientific investigation aims or should aim, if there is to be a purpose to a scientific study of culture at all.

Object-Oriented (OO) Programming

Linda Sherrell

Department of Computer Science, The
University of Memphis, Memphis, TN, USA

Object-oriented programming is a paradigm that was created to allow software engineers to build large software applications. The motivating factor was to have reusable components so that a programmer would not have to “reinvent the wheel” each time he or she needed a procedure to solve a subproblem. Furthermore, the developers of OO languages felt that important data or information and its associated operations should be grouped together for both readability and, more importantly, maintainability.

The programming language construct that allows for the combination of data and operations is known as a *class*. A class can specify an actual real-world item (e.g., Card) that one could touch or an abstract object (e.g., Holiday). Note that an *object* is an instance of a class.

A class has attributes or instance variables that are usually specified as `private` in Java. In other words, the data cannot be accessed or changed outside of the class without using methods. The access methods are called *getters*, whereas the methods that change the variables

are known as *setters*. The class itself is a template for each instance.

Below is an example of a class (with only the data defined), followed by two instances of the class. Note that most programming languages enclose string values in double quotes. The data type `double` indicates a value with a decimal point. Because it is a `double` rather than a `float`, more memory will be allocated allowing for better precision in calculations.

```
public class Card
    private String occasion
    private double price
```

BdayCard	AnnivCard
“Birthday”	“Anniversary”
1.49	4.95

Suppose we want to define a class to represent a card store. The data for the store can be modeled as an ADT List of Card objects. The List might be implemented as an array or as a linked list. Operations in this class might be the following:

- Add a card to the inventory (can be implemented using the List ADT operation `add`).
- Sell (can be implemented using the List ADT operation `remove`).

Obstetrics

James Drife

Department of Obstetrics and Gynaecology,
University of Leeds Leeds Teaching Hospitals
NHS Trust, Leeds, UK

Description

Obstetrics is the branch of medicine concerned with pregnancy and childbirth. Originally its sole concern was extraction of the child when labor became obstructed and its main objective was to preserve the mother’s life. The twentieth century, however, saw the introduction of

antenatal care, which treated maternal disease during pregnancy, and, in the second half of the century, techniques like amniocentesis and ultrasound scanning and fetoscopy which enabled obstetricians to examine and treat the fetus before birth. The subspecialty is now concerned as much with the baby as with the mother.

In developed countries, pregnancy has become very safe, but elsewhere, it carries high risks to mother and baby. Worldwide 600,000 women die because of pregnancy every year (AbouZahr and Wardlaw 2004) and in the poorest countries, particularly where there is conflict, the risk can be as high as 1 in 50 births. Almost all these deaths could be prevented by standard obstetric care. Many agencies including the World Health Organization are trying to address this problem (World Health Organization 2004), but the solution is more political than medical.

In developed countries, cesarean section rates are rising. Rates of over 20% are now common and are causing concern. Other recent developments include screening to detect fetal abnormalities, using ultrasound examination and maternal blood tests. In future, it may be possible to assess the fetus's genetic makeup by examining fetal cells in maternal blood (Kumar and O'Brien 2004). Fetal surgery is an option for only a very small number of conditions and medical treatment also has limited applications, so screening often leads to abnormal fetuses being aborted.

Self-identification

Science

Obstetrics self-identifies as a science although in some ways it is a craft, like surgery. It has elements of epidemiology, with its focus on rates of maternal mortality, perinatal mortality, cesarean section, etc. Techniques such as ultrasound scanning and prenatal diagnosis are based on sciences such as physics and molecular biology. With the rise of evidence-based medicine in the 1990s (see below), obstetrics in Western countries has

become concerned that all treatments should be justified by randomized controlled trials. This is important in countries such as the UK and the USA where there is now a backlash against what is seen as excessive medicalization of childbirth.

Characteristics

In obstetrics, there are two patients to consider and sometimes their interests conflict. For example, cesarean section may be safest for the baby but involves some risk to the mother. More than most medical specialties, obstetrics involves watching a natural process and deciding whether or not to intervene. Unlike many specialties – brain surgery, for example – nonmedical people feel they have a good understanding of the subspecialty and may have firm views about what the practitioner ought to do.

Relevance to Science and Religion

The subdiscipline is concerned with the beginning of life, and this raises ethical questions which demand practical answers. Science provides information such as the genetic makeup and gender of the fetus, the presence of abnormalities, and the risk of future disease which may affect the quality of life of the child, parents, and siblings. The parents' wishes may conflict with the doctor's religious principles. Conversely, the religious principles of the patient and her relatives – for example, refusal of blood transfusion – may put a woman's life at risk and cause great distress to her doctors.

Sources of Authority

For most of its history, the subdiscipline has relied on teaching passed on from senior practitioners through textbooks, lectures, and day-to-day instruction. The first obstetric textbook was *Der Schwangeren Frauen und Hebammen Rosengarten*, known as “the Rosengarten,”

written by Eucharius Rosslin, and published in Germany in 1513. It restated the obstetric teaching of the ancients, including Soranus of Ephesus. At that time childbirth was the responsibility of midwives and in the sixteenth century the French surgeon Ambroise Pare founded a school for midwives in Paris. In the seventeenth century, “accoucheurs” (man-midwives) became fashionable in France. In 1752 a Scotsman, William Smellie, practicing midwifery in London, published his *Treatise on the Theory and Practice of Midwifery*, including a description of obstetric forceps. He has become known as “the master of British midwifery” but was violently opposed by the London midwives (Drife 2002). Tension between the professions still continues.

In Britain, “midwifery” became a compulsory subject for medical students in the nineteenth century and university chairs were established. For example, James Young Simpson, who introduced chloroform anesthesia, was appointed Professor of Midwifery in Edinburgh in 1840. In the twentieth century the main sources of authority were professors and other senior practitioners. Although their opinions were not always in agreement, their teaching was respected because obstetrics had developed through a process of trial and error, and practitioners had learned through bitter experience. Juniors were naturally anxious to avoid repeating the errors of their predecessors.

At the end of the twentieth century, with the rise of evidence-based medicine, this style of teaching was ridiculed as old-fashioned. Evidence-based medicine involves rigorously designed clinical trials with precautions to exclude bias and achieve objectivity. It has been widely accepted in Western obstetrics. One difficulty is that large numbers of subjects are required if a trial is examining risks which are already low. This has led to the technique of “meta-analysis,” in which the results of several trials, each inconclusive, may be combined to give a statistically significant result (King 2005).

It has become impossible for individual practitioners to assess the evidence on every question,

and obstetricians are relying increasingly on guidelines produced by their professional bodies, such as the American College of Obstetricians and Gynecologists and, in the UK, the Royal College of Obstetricians and Gynaecologists (Royal College of Obstetricians and Gynaecologists and Royal College of Midwives 1999). These are well respected internationally. In many countries, guidelines are produced by state-controlled bodies including, in post-Soviet countries, the Ministry of Health. Such guidelines may still be based on traditional teaching rather than evidence.

Ethical Principles

Like other medical specialties, obstetrics is guided by the Hippocratic Oath and the Declaration of Helsinki but this guidance is not absolute. The Hippocratic Oath includes the promise “I will not give a woman a pessary to cause abortion” but even obstetricians who disagree with abortion may feel it is justified in a case of lethal fetal abnormality.

The principles that underpin modern medical ethics (Beauchamp and Childress 2001) are: “Respect autonomy,” “Maximize beneficence,” and “Act Justly.” Respecting autonomy means that decisions are made by the woman herself. For example, a woman cannot be forced to have a cesarean section even if her refusal means that the fetus will die. However, the three principles may conflict with one another – for example, when a woman demands an intervention which puts her or her baby at risk. Balancing autonomy, beneficence, and justice is the job of each obstetrician.

Specific guidance on ethical matters is set out in some countries by bodies that govern the medical profession, such as the General Medical Council in the United Kingdom (General Medical Council 2006). Professional bodies such as the British Medical Association also offer ethical guidance which is not binding on members.

Key Values

Preservation of the life and health of the mother is the most basic aim of obstetrics (Lewis 2007), and in the last analysis it takes precedence over the life and health of the baby. The emotional quality of the birth experience is becoming increasingly important in developed countries. Sometimes the aim of minimizing risk can conflict with the aim of optimizing the ideal birth experience.

Conceptualization

Nature/World

Obstetricians try to work with nature and to ensure that their interventions, if required, mimic nature as much as possible. Nevertheless, the purpose of medicine is to combat nature when natural processes, such as infection, are harmful to humans. The process of combating or manipulating nature begins by understanding it as fully as possible.

Human Being

Obstetricians have the privilege of observing the creation of human beings from a cell that develops into an embryo, then into a fetus, and finally a baby. The point during this process at which the term “human being” can be applied is debatable. The heart begins to beat about 3 weeks after conception but the brain’s cerebral cortex is still developing during the second half of pregnancy. Obstetricians are conscious of the potential of the embryo from the earliest stages of pregnancy but generally take the view that the embryo and fetus gradually acquire the characteristics and rights of a human being.

Life and Death

The law defines birth as the origin of life but biology sees life as a continuum in which DNA inhabits many forms – in sperm or eggs, in the embryo, and so on. Where life came from in the first place is a question on which the subspecialty has no fixed opinion.

Reality

Obstetricians are firmly connected to the realities of life and death. Sudden emergencies demand practical action and small errors can have major consequences, so the subspecialty tends to be strong on practicalities and weak on philosophy.

Knowledge

A distinction is often made between information, knowledge, and wisdom. Much scientific information is now available to obstetricians, who increasingly use the internet to access it. Knowledge is the ability to put this information into context. Some patients want only knowledge, to help them make their own decisions. Others want the benefit of the doctor’s wisdom, which means interpreting knowledge in the light of experience, and understanding the needs of the individual patient.

Truth

Nature’s unpredictability means that obstetricians are suspicious of the concept of truth. Scientific “truth” is still very limited. Religious “truth” is more comprehensive but may be compromised by reality.

Perception

Perception may be a physical or an intellectual process. Perception of risk, for example, varies widely among different people. Perceptions of obstetrics itself vary, with some people perceiving obstetricians as doctors who save lives while others see them as interfering needlessly with a natural process and motivated by power or profit.

Time

Daytime and nighttime are the same for obstetricians – indeed, left to themselves, more babies are born at night than during the day. Time can pass very slowly when an obstetrician is practicing the important art of doing nothing, but when intervention is required, action may need to be very prompt. Much expensive litigation is concerned with determining the exact time-course of events around birth and trying to decide whether or not delivery a few minutes earlier may have prevented brain damage.

Consciousness

For the mother, awareness of her surroundings is important and if cesarean delivery is required every effort is made to use regional analgesia rather than general anesthesia. Fetal consciousness is hard to define. It requires a functioning cerebral cortex but even in late pregnancy, the fetus has few stimuli to interpret or learn from. Nevertheless there is evidence that the fetus at term can learn in the womb (Van Heteren et al. 2000).

Rationality/Reason

During pregnancy obstetricians and their patients discuss facts, options, probabilities, and risks in a rational and reasonable way. During labor, it can be harder for women and their partners to think rationally. This makes it important to discuss options in advance if possible, so that valid consent for interventions can be given.

Mystery

The more we know about human development, the more questions emerge. Creation of a human being from a single cell in only 9 months, without any outside help apart from the uterine environment, is arguably the greatest mystery imaginable. In spite of the down-to-earth practicality of their job, obstetricians retain a sense of wonder at this process and are profoundly aware of how little they understand it or can control it.

Relevant Themes

Obstetrics is a “broad church” which includes diverse views on science and religion. If there is a relevant additional theme, it is that of harmony. Obstetricians with divergent and indeed opposing views generally work easily together, accepting that both science and religion are necessary and seeing them as complementary and not opposing forces.

Description

Occupational therapy (OT) is a profession concerned with promoting health and well-being through occupation. The primary goal of occupational therapy is to enable people to participate in the activities of everyday life (World Federation of Occupational Therapists 2008). Founded in 1917, occupational therapy is a well-established profession internationally that uses everyday activities with people to improve or regain the capacity to participate in a meaningful and satisfying life. The term “occupation” means engagement in life activities and includes, activities necessary to care for self and others, education, work, play, leisure, and social participation. Occupational therapy is practiced in a wide range of settings, including hospitals, health centers, mental health centers, community centers, homes, workplaces, schools, and housing for seniors. Clients are actively involved in the therapeutic process, and outcomes of occupational therapy are client driven and measured in terms of participation or satisfaction derived from participation (World Federation of Occupational Therapists 2008; Townsend and Polatajko 2007).

Occupational Performance Model

Occupational Therapy, Fig. 1 Occupational Performance Model: The concept of occupational performance has become mainstay in the development of models of occupational therapy. It operates as a means of connecting the individual to roles and to the sociocultural environment (Reed and Sanderson 1999, p. 93). Occupational therapists practice from an occupational performance perspective which requires the practitioner to know: what do people do in their daily lives, what motivates them, and how their personal characteristics combine with the situations and environments in which their occupations are undertaken

Recent advances include: development of models of occupational performance (Fig. 1) (Reed and Sanderson 1999; Christiansen et al. 2005) and enabling occupation (Townsend and Polatajko 2007); adoption of client-centered approaches; movement away from interventionalist to self management strategies; endorsement of the World Health Organisation International Classification of Functioning, Disability and Health (World Health Organization 2001); and focus on activity participation and ongoing challenges to productive lifestyles. There are currently over 50 member countries of the World Federation of Occupational Therapists (WFOT).

Self-identification

Science

Occupational therapy has over the past decades achieved the criteria of a science discipline. It has established its own literature focused on testing
